

# Safety Methods Database

Version 1.2

3 November 2020

Maintained by NLR

**Editors:** Mariken H.C. Everdij (NLR), Henk A.P. Blom (NLR)

**Contributions by:** Michael Allocco (FAA), David Bush (NATS), Mete Çeliktin (Eurocontrol), Barry Kirwan (Eurocontrol), Patrick Mana (Eurocontrol), Jochen Mickel (Goethe University), Keith Slater (NATS), Brian Smith (NASA), Oliver Sträter (Eurocontrol), Edwin Van der Sluis (NLR)

**Additions can be sent to [everdij@nlr.nl](mailto:everdij@nlr.nl)**

This document gives an overview of Techniques, Methods, Databases, or Models that can be used during a Safety Assessment. This is a living document. Additions are welcome.

**Please feel free to share the material. If the material is being used, please refer to it as:**

- M.H.C. Everdij and H.A.P. Blom, Safety Methods Database. Version 1.2, November 2020. Maintained by Netherlands Aerospace Centre NLR, The Netherlands. Available at <http://www.nlr.nl/documents/flyers/SATdb.pdf>

This document consists of three parts:

## ***Part 1: Overview of Safety Methods***

This part, which starts on page 5, contains a table listing all Safety Methods collected, with for each method the following information provided (if available):

- **Method name**, i.e. Acronym and name.
- **Format**, specifies the general format of the method, e.g. whether it is a stepped approach, or a mathematical model, or a combination of various techniques, etc. See Table 1 below for the list of formats defined.
- **Purpose**, specifies the primary purpose of the method, e.g. whether it is for data gathering, for hardware dependability analysis, for human reliability analysis, etc. See Table 2 below for the list of purposes defined.
- **Year**, i.e. year of development of the method. If uncertain, then words like ‘about’ or ‘or older’ are added.
- **Aim/description** of the method. This description is very brief; one is referred to the references for a more complete description.
- **Remarks**, such as links to related methods.
- **Safety assessment stage**, which lists the stages of a generic safety assessment process, proposed in [SAP 15], during which the method can be of use. These stages are: **1)** Scope the assessment; **2)** Learning the nominal operation; **3)** Identify hazards; **4)** Combine hazards into risk framework; **5)** Evaluate risk; **6)** Identify potential mitigating measure to reduce risk; **7)** Safety monitoring and verification; **8)** Learning from safety feedback.
- **Domains**, i.e. the domains of application the method has been used in, such as nuclear, chemical, ATM (air traffic management), rail, healthcare. See Table 3 below for the list of domains defined. Methods with a domain that is underlined are found to be exclusive for that domain. For domains between brackets (..), there is an indication that the method is applicable to that domain, but no proof is found yet that the method has been actually used in that domain. See also Table 4 for explanations.
- **Application**, i.e. is the method applicable to hardware, software, human, procedures, or to organisation.
- **References used**. Note that the reference lists are not exhaustive. The codes are explained in Part 3.

## ***Part 2: Statistics***

This part, which starts on page 230, gathers some statistics on the number of occurrences of elements in the table of Safety Methods, e.g. number of occurrences of ‘aviation’ as a Domain, number of occurrences of ‘Identify hazards’ as a Safety assessment stage.

## ***Part 3: References***

This part, which starts on page 239, gives the full list of references used.

Table 1: Classes defined for Format column:

|      |   |
|------|---|
| Gen  | Generic term or principle or theory, rather than a specific technique             |
| Step | Stepped approach or technique or specific way of working                          |
| Tab  | Static approach with tabular, checklist or questionnaire support                  |
| Stat | Static model or approach with graphical support (e.g. flow charts, trees, graphs) |
| Dyn  | Dynamic model with graphical support, often with mathematical base                |
| Math | Mathematical formalism or expression, with no or limited graphical support        |
| Int  | Framework or Integrated method of more than one technique                         |
| Dat  | Database or data collection tool  |
| Min  | Data analysis tool or data mining tool  |
| RTS  | Real-time simulation  |
| FTS  | Fast-time simulation  |

Table 2: Classes defined for Purpose column:

|      |  |
|------|--|
| Mod  | Developing a model (e.g. as input to or as part of analysis)   |
| Par  | Parameter value assessment (e.g. human error probabilities, failure frequencies)                               |
| HRA  | Human Reliability Analysis or Human Error analysis method  |
| HFA  | Human Factors Analysis (beyond reliability; e.g. behaviour, situation awareness)                               |
| Task | Human Task analysis  |
| Trai | Training technique or method to analyse training   |
| Des  | Design technique (about making/ensuring a safe design, rather than about analyzing whether the design is safe) |
| Dec  | Decision-making  |
| SwD  | Software dependability analysis or Software testing technique  |
| HwD  | Hardware dependability analysis (reliability, maintainability, availability, etc)                              |
| OpR  | Risk analysis of an operation or of a safety-critical scenario   |
| Org  | Organisation, Safety management, or Safety culture assessment  |
| Dat  | Data collection and information sharing  |
| Mit  | Mitigation of risk   |
| Hzi  | Identification of hazards /safety concerns /causes /issues   |
| HZA  | Identification and analysis of frequency and/or severity of hazards / safety concerns / causes / issues        |
| Col  | Collision risk analysis or Conflict risk analysis, typically between aircraft                                  |
| Val  | Validation, Verification, Bias and uncertainty analysis, Documentation/Tracking, and Oversight/Monitoring      |
| Ret  | Retrospective accident or event analysis   |

Table 3: Classes defined for Domain column:

|                 |   |
|-----------------|---|
| Aviation        | Operation of individual aircraft or aircraft fleets, including pilot and crew factors and airline operations  |
| Airport         | Airport operations and airport design   |
| ATM             | Air traffic management and air traffic control operations and equipment   |
| Aircraft        | Aircraft technical systems and airworthiness issues. Also including rotorcraft such as helicopters.   |
| Avionics        | Aviation electronics, i.e. electronic systems used on aircraft, satellites, and spacecraft, including communication, navigation, cockpit display.   |
| Defence         | Military, on land or in the air, including military aviation, weapon systems and nuclear weapon systems. Excluding military at sea.   |
| Navy            | Navy, military at sea, including sub-marines  |
| Space           | Space safety, including spacecraft, satellites, space missions. Excluding aircraft, excluding avionics.   |
| Rail            | Rail transport and operation of trains, including railway design. Excluding manufacturing of trains.  |
| Road            | Road transport and operation of cars, including road design, tunnels. Excluding manufacturing of cars.  |
| Maritime        | Marine, maritime or inland water transport, e.g. ships, vessels, ferry's, and coast guard search and rescue. Excluding navy, sea pollution, oil spills.   |
| Nuclear         | Nuclear power industry. Excluding nuclear weapon systems.   |
| Energy          | Energy or electricity-generating plants, solar energy, windturbines, thermal power plants. Excluding nuclear power.   |
| Chemical        | Chemical industry and processes, including production of medicine, biochemical industry. Excluding oil&gas, petrochemical, food and beverages.  |
| Oil&gas         | Oil and/or gas industry, including offshore oil&gas industry, petrochemical industry  |
| Manufacturing   | Manufacturing plants, including automotive or automobile manufacturing, construction of buildings, ship building, and process industry (i.e. processing of bulk resources into other products). Excluding food, chemical or petrochemical industry. |
| Healthcare      | Health care, hospitals, nursing, medical operations, biomedical issues. Excluding production of medicine and other chemicals, and excluding ergonomics.   |
| Environment     | Environment safety, e.g. air pollution, sea pollution, fuel and oil spills, wastewater treatment plants, fish and wildlife reserves, biology, earthquakes, water management   |
| Food            | Food and beverages, including public water supply systems, agriculture  |
| Mining          | Mining industry   |
| Social          | Psychology, psychometrics, behavioural sciences, social sciences, education, safety culture studies.  |
| Ergonomics      | Ergonomics, i.e. workplace equipment design, intending to reduce operator fatigue and discomfort. Also including household safety   |
| Finance         | Finance, banking, insurance, economics  |
| Management      | Management and organisation, including project management, information management, product management, marketing, operations research, logistics  |
| Security        | Security, i.e. dealing with protection from harm due to intentional criminal acts such as assault, burglary or vandalism. Excluding police and fire fighting  |
| Leisure         | Leisure and amusement industry, amusement parks, games, video games, media (e.g. tv advertisements), leisure-related search and rescue  |
| Police          | Police and Fire fighting, Search and rescue, including forensics and law.   |
| Electronics     | Electronics, electronic equipment, telecommunications, digital forensics  |
| Software        | Method has been applied to software design or analysis, but the industry sector in which the software is actually used is unclear or unspecified.   |
| No-domain-found | No applications were found (yet) for this method, not even in an example illustration, so that the domain is currently unclear.   |
| All             | There are a few approaches that are very generic and that have been used in virtually all domains.  |

Table 4: Codes regarding Domain column:

|                 |  |
|-----------------|--|
| domain          | Found proof or strong indication that method has in fact been applied in this domain (note that this proof is not necessarily provided in this document)   |
| <u>domain</u>   | Ditto; method appears to be for use in this domain exclusively   |
| (domain)        | Found indication that the method is intended for application in this domain, but found no strong indication (yet) that the method has in fact been applied. For instance, the method name refers to a domain, the method is mentioned in a domain-specific document, or an application of the method is a theoretical example. |
| <u>(domain)</u> | Ditto; method appears to be for use in this domain exclusively   |

## Document control sheet

| Version | Date              | Main changes   | Number of methods in database                                |
|---------|-------------------|--|--|
| 1.2     | 3 November 2020   | Descriptions of 19 new methods added plus 2 alternative names to already listed methods.   | 866 methods (plus 177 links or alternative names to methods) |
| 1.1     | 31 August 2016    | Rigorous re-classification and update of Format and Purpose of all methods. Rigorous re-classification and update of Domain of all methods, now also distinguishing between method being applicable in domain versus actually applied in domain. Addition of several new methods. Some similar methods are combined. Update of some details in other columns. Some references added.   | 847 methods (plus 175 links or alternative names to methods) |
| 1.0     | 4 March 2013      | Description and classification of many methods improved. Many new methods added, primarily identified as part of a project on safety methods conducted by NLR for the U.S. Federal Aviation Administration in 2011-2012.   | 807 methods (plus 162 links or alternative names to methods) |
| 0.9     | 7 December 2010   | Description and classification of many methods improved. 69 new methods added. 66 methods added without number but with reference to other methods. 15 methods removed with reference to other methods. For 32 methods, number and description removed, with reference to other methods. Update of statistics. Verification and update of all URLs in list of references and many references added. Introduction of a new classification type (in column Purpose) which collects Design (D) techniques, which are aimed at designing rather than analysing with respect to safety. | 726 methods (plus 150 links or alternative names to methods) |
| 0.8     | 31 January 2008   | Descriptions of 19 new methods added plus 3 alternative names to already listed methods. New classification type introduced (in column Purpose), which collects (O) Organisation techniques. This class now includes about 20 methods, most of which were previously classified as (H) Human performance analysis technique, five were previously (R) Risk assessment techniques; two were (M) hazard Mitigating techniques.   | 701 methods (plus 53 links or alternative names to methods)  |
| 0.7     | 20 February 2007  | Descriptions of 31 new methods added. Alternative names or links to 49 methods included as separate entries in the table, with link to the original method, and without additional details provided. Details for one method removed and replaced by link to same method by alternative name. Minor details for many other methods updated.   | 682 methods (plus 50 links or alternative names to methods)  |
| 0.6     | 28 November 2006  | One method added. Update of statistics and minor details of other methods.   | 652  |
| 0.5     | 28 August 2006    | One method added. Update of statistics and minor details of other methods.   | 651  |
| 0.4     | 27 April 2006     | 24 methods added from various sources. Textual changes and updates of other methods. Insert of statistics on database attributes.  | 650  |
| 0.3     | 31 March 2005     | Update, supported by the project CAATS [CAATS SKE II, 2006]. Ninety-nine methods added, mainly from references [GAIN ATM, 2003] and [GAIN AFSA, 2003]. Textual changes and updates of all methods.   | 626  |
| 0.2     | 26 November 2004  | Update, supported by the project CAATS [CAATS SKE II, 2006]. Seven methods added, and for all methods an assessment provided of the applicable Safety Assessment Stages.   | 527  |
| 0.1     | 24 September 2004 | Initiation of database, with 520 methods gathered during the EEC funded and supported project [Review SAM Techniques, 2004].   | 520  |

## Part 1: Overview of Safety Methods

(For explanation of table headers, see first pages of this document.)

| Id | Method name                            | Format | Purpose | Year | Aim/Description  | Remarks  | Safety assessment stage |   |   |   |   |   |   |   | Domains | Application |  |        |        |        | References |  |  |  |  |  |
|----|--|--------|---------|------|--|--|-------------------------|---|---|---|---|---|---|---|---------|-------------|--|--------|--------|--------|------------|--|--|--|--|--|
|    |  |        |         |      |  |  | 1                       | 2 | 3 | 4 | 5 | 6 | 7 | 8 |         | H<br>w      | S<br>w   | H<br>u | P<br>r | O<br>r |            |  |  |  |  |  |
| 1. | @RISK                                  | FTS    | Dec     | 1991 | @RISK uses the techniques of Monte Carlo simulation for Bias and Uncertainty assessment in a spreadsheet-based model. Four steps: (1) Developing a Model – by defining a problem or situation in Excel spreadsheet, (2) Identifying Uncertainty – in variables in Excel spreadsheets and specifying their possible values with probability distributions, and identifying the uncertain spreadsheet results that are to be analyzed, (3) Analyzing the Model with Simulation – to determine the range and probabilities of all possible outcomes for the results of the worksheet, and (4) Making a Decision – based on the results provided and personal preferences.   | Developed by Palisade. @RISK evolved from PRISM (this is another than the PRISM elsewhere in this database), released by Palisade in 1984, which also allowed users to quantify risk using Monte Carlo simulation. See also Monte Carlo Simulation.  |                         |   |   |   |   | 5 |   |   |         |             |  |        |        |        |            |  |  |  |  | <ul style="list-style-type: none"> <li>[GAIN ATM, 2003]</li> <li>[GAIN AFSA, 2003]</li> <li>[FAA HFW]</li> </ul>                                     |
| 2. | 3CA<br>(Control Change Cause Analysis) | Step   | Ret     | 2000 | In 3CA, accidents and incidents are treated as a sequence of events, beginning with the moment that control is reduced and ending with the moment that control is restored. Some of the events in the sequence are 'significant', i.e. they increase risks or reduce control, so allow further unwanted changes to occur. Steps are: 1) identify these significant events, making explicit who/what is acting, the action and who/what is acted upon. 2) identify what measures could have prevented the events or limited their effects, and in what ways prevention was ineffective. Here, the focus is on tangible barriers and controls, those at the operational level. 3) identify the differences between what was expected (based on norms such as standards and procedures) and what was true in the actual situation. 4) Explain these differences in terms of organisational and cultural factors that influenced the situation and in terms of the systems and management arrangements that caused or allowed the difference to exist. | 3CA was developed by Humber Chemical Focus and the UK Health & Safety Executive (HSE) in 2000. This original version is sometimes referred to as 3CA Form-A. Later versions, by Noordwijk Risk Initiative Foundation, are referred to as Form-B (developed in 2007) and Form C (developed in 2009); the latter includes a graphical worksheet. 3CA is based on a generalised form of energy trace and barrier analysis (ETBA). |                         |   |   |   |   |   |   |   |         | 8           | road, police, chemical, manufacturing, food, (nuclear) |        |        |        |            |  |  |  |  | <ul style="list-style-type: none"> <li>[Ziedelis &amp; Noel, 2011]</li> <li>[Kingston, 2002]</li> <li>[Wu &amp; Zongxiao &amp; Lei, 2016]</li> </ul> |

| Id | Method name                                       | Format | Purpose | Year        | Aim/Description   | Remarks  | Safety assessment stage |   |   |   |   |   |   |   | Domains | Application |   |        |        |        | References |   |   |  |
|----|---|--------|---------|-------------|---|--|-------------------------|---|---|---|---|---|---|---|---------|-------------|---|--------|--------|--------|------------|---|---|--|
|    |   |        |         |             |   |  | 1                       | 2 | 3 | 4 | 5 | 6 | 7 | 8 |         | H<br>w      | S<br>w  | H<br>u | P<br>r | O<br>r |            |   |   |  |
| 3. | 3-D Collision Risk Model                          | Math   | Col     | 1999 from   | The Eurocontrol 3-D collision risk model aims at providing a means for assessing the Level of Safety in (European) en route airspace, where controllers monitor air traffic by means of radar and provide tactical instructions to aircraft. A supporting prototype software tool analyzes recorded aircraft tracks from Radar Data Processing systems within a time span and a given volume of airspace, in order to identify all proximate events (conflicts, potential conflicts, and potential collisions), classifies them according to various criteria, estimates the frequency of occurrence of these events, and determines the different parameters needed to estimate the probability of aircraft being on a collision course and the probability of air traffic control-loop resolution failure.  | The work to develop the 3-D collision risk model has been accomplished under several Eurocontrol contracts since 1999.   |                         |   |   |   |   | 5 |   |   |         |             |   | ATM    |        |        |            | x |   | <ul style="list-style-type: none"> <li>[Burt, 1999]</li> <li>[Burt, 2000]</li> <li>[INECO, 2006]</li> <li>[Garcia et al, 2007]</li> <li>[Mehadhebi, 2007]</li> <li>[Saez et al, 2010]</li> </ul> |
|    | 3D-SART (3D-Situation Awareness Rating Technique) |        |         |             |   | See SART. Applicable to aircrew.   |                         |   |   |   |   |   |   |   |         |             |   |        |        |        |            |   |   |  |
| 4. | 5M Model or 5-M Factors                           | Stat   | Mod     | 1949 - 1976 | The 5M Model is aimed at describing or examining a proposed change, a system, or a particular accident in a structured way. It assists in deconstructing the proposed change (or system or accident) elements that are later input to the structured identification of the sources, causes, hazards, and current and proposed hazard mitigation strategies related to the proposed change (or system or accident). The five Ms are: 1) Mission: the purpose or central function of the system, the reason that all the other elements are brought together; 2) Man: the human element of a system. 3) Machine: the hardware and software (including firmware) element of a system. 4) Management: includes the procedures, policy, and regulations involved in operating, maintaining, installing, and decommissioning a system. 5) Media: the environment in which a system will be operated, maintained, and installed, it includes operational and ambient conditions. | The 5M Model of System Engineering is commonly depicted as three circles, one each for Man, Machine and Media, which partially overlap. Mission is in the area in which all three circles overlap. Surrounding the combination of three circles is another circle for Management. In FAA references, the locations of Management and Media are interchanged (making Media the surrounding circle). The first triple of M's (Man, Machine, Media) was proposed by T.P. Wright of Cornell University in the late 1940s. Management was introduced in 1965 at University of Southern California. Mission was introduced in 1976 by E.A. Jerome, Flight Safety Foundation. | 1                       | 2 |   |   |   |   |   |   |         |             | aviation, ATM, oil&gas, defence, finance  | x      | x      | x      | x          | x | <ul style="list-style-type: none"> <li>[FAA00]</li> <li>[ATO SMS Manual v3.0]</li> <li>[Wells &amp; Rodrigues, 2001]</li> <li>[DotAF, 5M Model]</li> <li>[CAPGORM]</li> <li>[AFP 90-902, 2000]</li> </ul> |  |
| 5. | ABMS (Agent Based Modelling and Simulation)       | Gen    | Mod     | 1949        | Agent-based modeling is a simulation modeling technique in which a system is modeled as a collection of interacting autonomous decision-making entities called agents. Each agent individually assesses its situation and makes decisions on the basis of a set of rules. Agents may execute various behaviours appropriate for the system they represent. Since the models typically feature repetitive complex behaviour patterns and competitive interactions between agents, their evaluation cannot be done analytically but is done by means of computer simulation.  | In safety analysis, ABMS is referred to as MA-DRM.   |                         |   |   |   | 4 |   |   |   |         |             | ATM, environment, social, management, road, finance, energy, healthcare, chemical, security | x      |        | x      | x          | x | <ul style="list-style-type: none"> <li>[Bonabeau, 2002]</li> <li>[Macal &amp; North, 2006]</li> <li>[Stroeve et al, 2013]</li> </ul>  |  |

| Id | Method name                                   | Format   | Purpose | Year          | Aim/Description   | Remarks   | Safety assessment stage |   |   |   |   |   |   |   | Domains  | Application |        |        |        |        | References |  |   |   |
|----|---|----------|---------|---------------|---|---|-------------------------|---|---|---|---|---|---|---|----------|-------------|--------|--------|--------|--------|------------|--|---|---|
|    |   |          |         |               |   |   | 1                       | 2 | 3 | 4 | 5 | 6 | 7 | 8 |          | H<br>w      | S<br>w | H<br>u | P<br>r | O<br>r |            |  |   |   |
| 6. | ABRM<br>(Analytic Blunder Risk Model)         | Math     | Col     | 1985          | ABRM is a computational model to evaluate the probability of a collision, given a particular blunder (controller error, pilot error, equipment malfunction) between one aircraft involved in the error (the “blunderer”) and another aircraft (the “evader”). ABRM considers both the probability of a collision assuming no intervention, and the probability of timely intervention by pilots or controllers. It uses empirical probability distributions for reaction times and a closed form probability equation to compute the probability that a collision will occur. This permits it to consider combinations of events with small probabilities efficiently and accurately.             | ABRM is programmed in Excel (with macros). Developed by Ken Geisinger (FAA) in 1985.  |                         |   |   |   |   | 5 |   |   |          |             |        | ATM    |        |        |            | x  |   | <ul style="list-style-type: none"> <li>• [Geisinger, 1985]</li> <li>• [GAIN ATM, 2003]</li> </ul>             |
| 7. | Absorbing boundary model                      | Math     | Col     | 1964          | Collision risk model. Reich-based collision risk models assume that after a collision, both aircraft keep on flying. This one does not. A collision is counted if a process state (usually given by a differential equation) hits the boundary of a collision area. After this, the process state is “absorbed”, i.e. does not change any more.   | Mainly of theoretical use only, since it requires a parabolic partial differential equation to have a unique solution.  |                         |   |   |   |   | 5 |   |   |          |             |        | (ATM)  |        |        |            | x  |   | <ul style="list-style-type: none"> <li>• [Bakker &amp; Blom, 1993]</li> <li>• [MUFTIS3.2-II, 1996]</li> </ul> |
| 8. | ACAT<br>(Air Carrier Assessment Tool)         | Tab      | Hzi     | 1999 or older | ACAT is used to assess an air carrier’s or applicant’s systems and operating environment for indications of hazards or conditions that may create hazards. This process helps to highlight any area on which to focus special oversight attention, and is used to prioritize the elements. The tool has 28 risk indicators, which let principal inspectors document concerns derived from information obtained through the Voluntary Disclosure Reporting Program (VDRP), Aviation Safety Action Program (ASAP) and Flight Operational Quality Assurance program (FOQA). These concerns are converted to a numerical score that is used to prioritize work assignments and re-target inspections. | Risk indicators are groupings of safety- and/or performance-related data that reflect areas of potential hazards and prioritize air carrier oversight plans. The two major categories for risk indicators (System Stability and Operational Risks) reflect the notion that internal and external events affect air carrier systems. Two subject areas further subdivide the categories. These subject areas focus the indicators on the operational, performance, and environmental risks most likely to impact an air carrier’s systems. |                         |   |   |   |   |   | 7 | 8 | aviation | x           |        |        |        | x      |            | <ul style="list-style-type: none"> <li>• [AV Glossary - ATOS]</li> <li>• [GAO, 1999]</li> <li>• [FAA FSIMS, 2009]</li> </ul> |   |   |
| 9. | ACCC<br>(Air Carrier Configuration Checklist) | Dat, Tab | Val     | 2007 or older | The Air Carrier Configuration Checklist is a series of questions that helps Certification Project Teams (CPT) and Certificate Management Teams (CMT) to document the air carrier’s or applicant’s scope of operation including factors such as type of operations, aircraft, facilities, personnel, equipment and operations specifications. This information is used for automated filtering of the oversight profile.   | For the checklist, see [FAA FSIMS, 2009], Page 29.  |                         | 1 | 2 |   |   |   |   |   | 8        | aviation    | x      |        | x      | x      | x          |  | <ul style="list-style-type: none"> <li>• [FAA FSIMS, 2009]</li> </ul> |   |

| 10. | Accident Analysis                    | Gen      | OpR     | 1992 or older | The purpose of the Accident Analysis is to evaluate the effect of scenarios that develop into credible and incredible accidents. Those that do not develop into credible accidents are documented and recorded to verify their consideration and validate the results. The process generally builds a database of factors such as Activity at the time of the accident; Distribution of incidents among personnel; Accident locations; Distribution of incidents by sub-unit; Patterns of unsafe acts or conditions. This database then serves as the basis to identify the risk drivers.  | Many methods and techniques are applied. E.g. PHA, Subsystem HA.   |                         |   |   | 3 | 4 | 5 |   |   |         |             |   | nuclear, aviation, chemical, ATM, space, rail, road, oil&gas, mining, healthcare, social | x      | x      | x          | x | x  | <ul style="list-style-type: none"> <li>• [FAA AC431]</li> <li>• [FAA00]</li> <li>• [ΣΣ93, ΣΣ97]</li> </ul> |

| 11. | AcciMapping                          | Stat     | Ret     | 1997          | Retrospective accident analysis technique that is used to identify and graphically represent the causal flow of events and the planning, management and regulatory bodies that may have contributed to a particular accident scenario. It also identifies decision makers who have the power to improve safety, and identifies relevant cross-disciplinary co-operation in research and design.  | Developed by Svedung & Rasmussen. A typical AcciMap comprises the following main levels: government policy and budgeting; regulatory bodies and associations; local area government planning and budgeting; company management, technical and operational management, physical processes and actor activities, equipment and surroundings. |                         |   |   | 3 | 4 |   | 6 |   |         | 8           | road, maritime, rail, oil&gas, ATM, police, healthcare, space, aviation | x  |        | x      | x          | x | <ul style="list-style-type: none"> <li>• [Rasmussen &amp; Svedung, 2000]</li> <li>• [Salmon et al, 2005]</li> <li>• [Qureshi, 2007]</li> </ul> |  |
| 12. | ACOP (Air Carrier Oversight Profile) | Dat, Tab | Hzi     | 2008 or older | This technique is a tailored list of elements, DCT (Data Collection Tool) questions, and job task items that are based on the specific regulatory requirements (SRR) that apply to the air carrier or applicant. Technique allows the principal inspector (PI) or certification project manager (CPM) to plan and conduct oversight activities that are specific to the air carrier's or applicant's system configuration. The PI or CPM can manually modify the profile in the event the air carrier has a unique situation that results in differences from the standard profile, such as a deviation or exemption. The PI or CPM must provide an explanation for all manual adjustments to the air carrier oversight profile. | Technique is applied early in the safety assessment process, during system description.  | 1                       | 2 |   |   |   |   |   |   |         | 8           | aviation  | x  |        | x      | x          | x | <ul style="list-style-type: none"> <li>• [FAA FSIMS, 2009]</li> </ul>  |  |

| 13. | ACS<br>(Airworthiness Concern Sheet)            | Dat    | Dat, Mit | 2000 about    | An ACS is intended as a means for FAA Aviation Safety Engineers to coordinate airworthiness concerns with aircraft owner/operators. When informed of a safety or airworthiness concern, the FAA engineer will complete an ACS detailing the available information, and send the ACS to the appropriate associations and type clubs, who disseminate the ACS to their members. Feedback information on technical and cost impact is compiled and submitted back to FAA, who develops appropriate corrective action. This action could involve an Airworthiness Directive (AD) or a Special Airworthiness Bulletin (SAIB), or the FAA could determine that no action is needed at that time.          |   |                         |   |   |   |   |   |   |   |         | 8           | aircraft                    | x      |        |        |            |   |  | • [SADAD Manual]                              |

| 14. | ACT<br>(Activity Catalog Tool)                  | Dat    | Dat      | 1993          | ACT provides instant, real-time statistical analysis of an observed sequence, including such measures as frequency of occurrence, duration of activity, time between occurrences and probabilities of transitions between activities. ACT automatically creates a data-log file that provides a detailed description of all observations, as well as a further important statistical description of the concurrence of events and activities. To allow for multiple observers and/or multiple observations of a given video tape, data-log files can be merged and/or appended using simple post processing functions.  | ACT was designed by two human factors experts (L. Segal and A. Andre, co-founders of Interface Analysis Associates (IAA)), who designed this tool for use for analysing pilot performance in the cockpit, analysis of computer workstations, evaluation of consumer products and graphical user interfaces. |                         | 2 | 3 |   | 5 |   |   |   |         |             | (ergonomics),<br>(aviation) |        |        | x      |            |   |  | • [FAA HFW]<br>• [ACT web]                    |
| 15. | ACTA<br>(Applied Cognitive Task Analysis)       | Tab    | Task     | 1997          | ACTA aims at identifying cognitive demands and skills required for a task, which can then be used to improve training or provide interface design recommendations. It consists of three interview methods: 1. Task Diagram Interview - provides a broad overview of the task and highlights the difficult cognitive portions of the task. 2. Knowledge Audit - surveys the aspects of expertise required for a specific task or subtask. 3. Simulation Interview - allows to probe the cognitive processes of the subject matter expert within the context of a specific scenario. The interviews are followed by the creation of a cognitive demands table to consolidate and synthesize the data. | Development of ACTA was funded by the Navy Personnel Research and Development Center. Aims to be less resource-intensive than CTA.  |                         | 2 |   |   |   |   |   |   |         |             | defence, police             |        |        | x      |            |   |  | • [Militello&Hutton, 1998]<br>• [Alley, 2005] |
| 16. | Action Information Requirements                 | Stat   | Task     | 1986 or older | Helps in defining those specific actions necessary to perform a function and, in turn, those specific information elements that must be provided to perform the action. It breaks up the references function requirement into useful groupings of action requirements and information requirements.   | Procedure for developing or completing action/information requirements forms is much more informal than that for most analysis methods.   |                         | 2 |   |   |   |   |   |   |         |             | aviation,<br>defence        |        |        | x      | x          | x |  | • [MIL-HDBK, 1999]<br>• [HEAT overview]       |

| 17. | Activity Sampling                              | Dat    | Task    | 1950 | Method of data collection which provides information about the proportion of time that is spent on different activities. By sampling an operator's behaviour at intervals, a picture of the type and frequency of activities making up a task can be developed.  | Cannot be used for cognitive activities.  |                         |   |   |   |   | 5 |   |   |         |             | manufacturing, healthcare, management |        |        | x      |            |  | <ul style="list-style-type: none"> <li>• [Kirwan &amp; Ainsworth, 1992]</li> <li>• [FAA HFW]</li> </ul>   |
| 18. | ACT-R (Adaptive Control of Thought - Rational) | FTS    | HFA     | 1993 | Simulates human cognition, using Fitts's (1964) three-step skill acquisition model of how people organise knowledge and produce intelligent behaviour. ACT-R aims to define the basic and irreducible cognitive and perceptual operations that enable the human mind. In theory, each task that humans can perform should consist of a series of these discrete operations. The three steps of this model are (1) the conversion of declarative input, (2) knowledge compilation and procedurisation, and (3) the result of both procedurisation and compilation. Procedure: Researchers create models by writing them in ACT-R, thus adopting ACT-R's way of viewing human cognition. Researchers write their own assumptions in the model and test the model by comparing its results to results of people actually performing the task.   | The original ACT was developed by J.R. Anderson in 1982. In 1993, Anderson presented ACT-R. There exist several University research groups on ACT-R. Typical for ACT-R is that it allows researchers to collect quantitative measures that can be compared with the quantitative results of people doing the same tasks. See also MoFL. See also HPM. |                         | 2 |   | 4 |   |   |   |   |         |             | social, navy                          |        |        | x      | x          |  | <ul style="list-style-type: none"> <li>• [FAA HFW]</li> <li>• [Anderson, 1982]</li> <li>• [Anderson, 1993]</li> <li>• [Fitts, 1964]</li> <li>• [Koubek, 1997]</li> <li>• [Leiden &amp; Best, 2005]</li> <li>• Many other refs at [Refs on ACT-R]</li> </ul> |
| 19. | ACWA (Applied Cognitive Work Analysis)         | Step   | HFA     | 2001 | ACWA systematically transforms the analysis of the cognitive demands of a domain into supporting visualisations and decision-aiding concepts. The first three (analysis) steps in this process relate to the analysis of the work domain: 1. Use a Functional Abstraction Network model to capture the essential domain concepts and relationships that define the problem-space; 2. Overlay Cognitive Work Requirements on the functional model as a way of identifying the cognitive demands / tasks / decisions that arise in the domain and require support; 3. Identify the Information / Relationship Requirements for successful execution of these cognitive work requirements. Subsequently, there are two design steps: 1. Specifying the Representation Design Requirements (RDR) to define the shaping and processing for how the information / relationships should be represented to practitioner(s); and 2. Developing Presentation Design Concepts (PDC) to explore techniques to implement the RDRs. PDCs provide the syntax and dynamics of presentation forms, in order to produce the information transfer to the practitioner(s). | Developed by W.C. Elm et al, Aegis Research Corporation. Successor to ACWA is referred to as ACSE (Applied Cognitive Systems Engineering).  |                         | 2 |   |   |   |   | 6 |   |         |             | defence, nuclear, leisure, social     |        |        | x      |            |  | <ul style="list-style-type: none"> <li>• [Elm et al, 2004]</li> <li>• [Gualtieri, 2005]</li> </ul>  |

The inspector certification program manager uses this tool to document the bottom-line design or performance assessment and the appropriate course of action for implementation.   |  |                         |   |   |   |   |   |   |   |         | 8           | (aviation) | x             |        |        |            |   |  | • [FAA FSIMS, 2009]                          |
| 22. | ADMIRA<br>(Analytical Dynamic Methodology for Integrated Risk Assessment) | Dyn    | OpR      | 1991          | ADMIRA is based on a Decision Tree approach. It utilises event conditional probabilities, which allows for the development of event trajectories without the requirement for detailed boolean evaluation. In this way, ADMIRA allows for the dynamic evaluation of systems as opposed to the conventionally available static approaches. Through a systematic design interrogation procedure it develops a complete series of logically linked event scenarios, which allows for the direct evaluation of the scenario probabilities and their associated consequences. Due to its interactive nature, ADMIRA makes possible the real time updating of the model of the plant/system under examination. | See also DTA (Decision Tree Analysis).   |                         |   |   |   | 4 | 5 |   |   |         |             | (nuclear)  | x             |        |        |            |   |  | • [Senni et al, 1991]                        |
| 23. | ADREP<br>(Accident Data REPorting system)                                 | Dat    | Dat      | 1975          | The ADREP system receives, stores and provides Contracting States with aircraft accident and incident data that will assist them in validating safety. The database includes worldwide accident/incident data from 1970 of aircraft (fixed wing and helicopter) heavier than 2250 kg. The data are submitted in a common reporting taxonomy.  | The ADREP system is operated and maintained by ICAO. Since 2004, it runs on the ECCAIRS software platform, which makes ADREP and ECCAIRS compatible. |                         |   |   |   |   |   |   |   |         |             | 8          | aviation, ATM | x      |        |            | x |  | • [ATSB, 2004]                               |
| 24. | ADSA<br>(Accident Dynamic Sequence Analysis)                              | RTS ?  | HRA      | 1994          | Cognitive simulation which builds on CREWSIM. Designed to identify a range of diagnosis and decision-making error modes such as fallacy, the taking of procedural short-cuts, and delayed response. Performance Shaping Factors (PSF) in the model are linked to particular Psychological Error Mechanisms (PEMs), e.g. PSF time pressure leading to the PEM of taking a short-cut. With this, the simulation approaches become (apparently) more able to generate realistic cognitive External Error Modes (EEMs) that have been observed to occur in real events and incidents.   |  |                         |   |   |   | 3 | 4 |   |   |         |             | (nuclear)  |               |        |        | x          | x |  | • [Kirwan, 1995]<br>• [Kirwan, Part 1, 1998] |

| 25. | AEA<br>(Action Error Analysis)                   | Tab    | HRA<br>,<br>Task | 1978                | Action Error Analysis analyses interactions between machine and humans. Is used to study the consequences of potential human errors in task execution related to directing automated functions. Very similar to FMEA, but is applied to the steps in human procedures rather than to hardware components or parts. The AEA worksheet contains the following columns: Task step; Cue; Action feedback / Effect feedback; Action error; Cause; Consequences; Risk; Suggested risk reduction actions and remarks.   | Developed at Risø National Laboratory in Denmark. Any automated interface between a human and automated process can be evaluated, such as pilot / cockpit controls, or controller / display, maintainer / equipment interactions. AEA can be executed for critical procedures during the detail design phase, but can also be executed for established procedures. AEA consists of AEMA and AECA, see also AEMA.  |                         |   |   | 3 |   | 5 |   |   |                              |             | oil&gas | x      |        | x      | x  |  | <ul style="list-style-type: none"> <li>• [FAA00]</li> <li>• [Leveson, 1995]</li> <li>• [MUFTIS3.2-I, 1996]</li> <li>• [ΣΣ93, ΣΣ97]</li> <li>• [Andersen, 2011]</li> <li>• [Taylor, 2013]</li> </ul> |
| 26. | AEB<br>(Accident Evolution and Barrier function) | Stat   | Ret              | 1991                | The AEB method models the interaction between human and technical systems. It consists of the narrative of the accident, the flow chart model of human and systems malfunctions, errors and failures, and barrier function analysis. The evolution leading to an accident evolution is modelled as a chain or sequence of malfunctions, failures, and errors in human and technical systems. Barrier functions represent functions which can arrest the accident evolution so that the next event in the chain is never realised.  | Developed by O. Svenson (Lund & Stockholm University). Method derived from HPES (human performance enhancement system). It is particularly focused on failures and errors. It can be used in predictive safety analyses as well as in post hoc incident analyses. In general, application of the model will indicate where and how safety can be improved, and it also raises questions about issues such as the cost, feasibility, and effectiveness of different ways of increasing safety. |                         |   |   |   |   | 6 |   | 8 | nuclear                      | x           |         | x      |        | x      | <ul style="list-style-type: none"> <li>• [Svenson, 1991]</li> <li>• [Ziedelis &amp; Noel, 2011]</li> </ul>                                   |  |   |
| 27. | AEMA<br>(Action Error Mode Analysis)             | Tab    | HRA<br>,<br>Task | 1994<br>or<br>older | Human errors for each task are identified using guidewords such as 'omitted', 'too late', etc. Abnormal system states are identified in order to consider consequences of carrying out the task steps during abnormal system states. Consequences of erroneous actions and abnormal system states are identified, as well as possibilities for recovery.   | Resembles Human HAZOP or FMECA. AEMA can be complemented by an Action Error Cause Analysis (AECA), which addresses identification of causes and contributing factors, and which can help to identify further error reduction measures for critical action error modes. AEMA plus AECA is called AEA. See also AEA.  |                         |   | 3 |   |   | 6 |   |   | oil&gas, (rail),<br>(energy) |             |         | x      |        |        | <ul style="list-style-type: none"> <li>• [Oien &amp; Rosness, 1998]</li> <li>• [Vinnem, 2000]</li> </ul>                                     |  |   |
| 28. | AERO<br>(Aeronautical Events Reports Organizer)  | Dat    | Dat              | 2003<br>or<br>older | Aim is to organise and manage incidents and irregularities in a reporting system, to provide graphs and reports, and to share information with other users. AERO is a FileMaker database developed to support the management of the safety department of aviation operators. AERO was created to enhance communication between the safety department and all employees, reduce paper handling, and produce reports. The Data Sharing program allows all AERO Certified Users to benefit from the experience of the other users. AERO users review their monthly events and decide which ones to share with the rest of the companies using AERO. | Safety Report Management and Analysis System  |                         |   |   |   |   |   |   | 8 | (aviation)                   | x           |         | x      | x      |        | <ul style="list-style-type: none"> <li>• [GAIN AFSA, 2003]</li> <li>• <a href="http://www.aerocan.com">http://www.aerocan.com</a></li> </ul> |  |   |

| 30. | AHP (Analytic Hierarchy Process)   | Stat   | Dec     | 1975 | Decision-making theory designed to reflect the way people actually think. Aims to quantify allocation decisions. The decision is first structured as a value tree, then each of the attributes is compared in terms of importance in a pairwise rating process. When entering the ratings the decision-makers can enter numerical ratios. The program then calculates a normalised eigenvector assigning importance or preference weights to each attribute. Each alternative is then compared on the separate attributes. This results in another eigenvector describing how well each alternative satisfies each attribute. These two sets of eigenvectors are then combined into a single vector that orders alternatives in terms of preference. | AHP was developed in the 1970's by Dr. Thomas Saaty, while he was a professor at the Wharton School of Business. Software support available (e.g. Expert Choice (EC)).   |                         | 2 |   | 4 | 5 |   |   |   |         |             | healthcare, nuclear, defence, oil&gas, chemical, environment, social, management, ATM |        |        | x      |            |   | <ul style="list-style-type: none"> <li>• [FAA HFW]</li> <li>• [Lehto, 1997]</li> <li>• [Maurino &amp; Luxhøj, 2002]</li> <li>• [Saaty, 1987]</li> <li>• [AHP tutorial]</li> </ul> |
| 31. | AHRA (All Hazards Risk Assessment)   | Int    | OpR     | 2011 | The purpose of the AHRA process is to assess and view risks in a standardized fashion using a common set of principles and steps. Steps are: 1. Setting the Context – Articulating an institution's objectives and defining its external and internal parameters to be taken into consideration when managing risks. 2. Risk Identification – Finding, recognizing, and recording risks. 3. Risk Analysis – Understanding the nature and level of risk, in terms of its impacts and likelihood. 4. Risk Evaluation – Comparing with risk criteria to determine whether a risk and/or its magnitude is acceptable or tolerable. 5. Risk Treatment – Identifying and recommending risk control or Risk Treatment options.                              | Scope is safety risks to the Canadian people requiring emergency planning by federal institutions, including thunderstorms, earthquakes, internet disruptions, disease outbreaks, train derailments, national security threats. For each step, the guidelines suggest various techniques that may be used. | 1                       |   | 3 | 4 | 5 | 6 |   |   |         |             | environment, security   |        |        |        |            | x | <ul style="list-style-type: none"> <li>• [PSC, 2012]</li> </ul>   |
| 32. | AHRQ approach (Agency for Healthcare Research and Quality approach)  | Tab    | Org     | 2004 | Survey on hospital patient safety culture. Measures seven unit-level aspects: Supervisor/ manager expectations and actions promoting safety; Organizational learning - continuous improvement; Teamwork within units; Communication openness; Feedback and communication about error; Non-punitive response to error; Staffing. In addition, the survey measures three hospital-level aspects of safety culture: Hospital management support for patient safety; Teamwork across hospital units; Hospital handoffs and transitions.  | Has been used in hospitals in and outside the US.  |                         |   |   |   |   |   |   |   |         |             | healthcare  |        |        |        |            | x | <ul style="list-style-type: none"> <li>• [Mkrtchyan &amp; Turcanu, 2012]</li> </ul>   |

| 40. | AIRS<br>(Aircrew Incident Reporting System)    | Dat    | Dat,<br>HRA | 1996                | AIRS is a confidential human factors reporting system that provides airlines with the necessary tools to set up an in-house human performance analysis system. It was established to obtain feedback from operators on how well Airbus aircraft operate to identify the significant operational and technical human performance events that occur within the fleet; develop a better understanding of how the events occur; develop and implement design changes, if appropriate, and inform other operators of the “lessons learned” from the events. AIRS aims to provide an answer to “what” happened as well as to “why” a certain incident and event occurred. The analysis is essentially based on a causal factor analysis, structured around the incorporated taxonomy. The taxonomy is similar to the SHEL model that includes environmental, informational, personal, and organisational factors that may have had an influence on crew actions. | AIRS is part of the Airbus Flight Operations Monitoring package. Over 20 airlines are using the system and several more are considering it. Based on BASIS software.                                     |                         |   | 3 |   |   |   |   |   | 7  | 8  | aviation,<br>aircraft |        |        | x      | x   | x  | <ul style="list-style-type: none"> <li>• [AIRS example]</li> <li>• [GAIN AFSA, 2003]</li> <li>• [Benoist]</li> </ul> |
| 41. | Analysable Programs                            | Gen    | Des         | 1984                | Aim is to design a program in a way that program analysis is easily feasible. The program behaviour must be testable completely on the basis of the analysis.  | Necessary if the verification process makes use of statistical program analysis techniques. Complementary to program analysis and program proving. Tools available. Software design & development phase. |                         |   |   |   |   | 6 |   |   |  | software                                 |                       | x      |        |        |   | <ul style="list-style-type: none"> <li>• [Bishop, 1990]</li> <li>• [EN 50128, 1996]</li> <li>• [Rakowsky]</li> </ul> |  |

| 47. | APRECIH<br>(Analyse PREliminaire des Conséquences de l'Infiabilité Humaine) | Tab    | HRA      | 1999 | Preliminary Analysis of Consequences of Human Unreliability. Focuses on the consequence assessment of human behavioural deviations independently of the probabilities of the occurrence of human errors. APRECIH classifies scenarios of unreliability using a three-dimensional cognitive model that includes: acquisition-based unreliability, problem solving-based unreliability and action-based unreliability. It consists of four consecutive steps: 1) Functional analysis of human-machine system; 2) Procedural and contextual analysis; 3) Identification of task characteristics; 4) (Qualitative) Consequence analysis.   | Design phase. In [Vanderhaegen, 2000], APRECIH has been integrated with a retrospective analysis step into a method named ACIH (a French acronym for Analysis of Consequences of Human Unreliability).   |                         |   |   | 3 | 4 | 5 |   |   |         |                                  | rail   |                         |        |        | x          |  |   | <ul style="list-style-type: none"> <li>• [PROMAIS, 2001]</li> <li>• [Vanderhaegen &amp; Telle, 1998]</li> <li>• [Vanderhaegen, 2000]</li> </ul> |  |
| 48. | AQD<br>(Aviation Quality Database)  | Dat    | Dat, Org | 1998 | AQD is a comprehensive and integrated set of tools to support Safety Management and Quality Assurance. Provides tools for data gathering, analysis and planning for effective risk management. AQD can be used in applications ranging from a single-user database to include operations with corporate databases over wide-area networks. AQD gathers Incident, Accident and Occurrence Reports together with internal and external quality and safety audits for joint analysis. It also offers tools for creating internal audit programs, assisting with audits for all airline departments, tracking corrective and preventive actions, integrating external audit requirements and analysing and reporting trends in quality indicators. | In [RAW, 2004], AQD is referred to as one of the big three Safety Event and Reporting Tools, along with BASIS and AVSiS. Ref. [GAIN GST03] refers to AQD as a clone of ASMS and states that AQD and ASMS are compatible in the sense that external organisations are able to gather their own occurrence data, track their own audit corrective actions, analyse the data and report their safety performance to CAA via an electronic interface. In practice, AQD is only used by larger organisations. Version 5 was released in 2005. |                         |   |   |   |   |   |   |   | 8       | aviation, ATM, airport, aircraft | x      |                         | x      | x      | x          |  | <ul style="list-style-type: none"> <li>• [GAIN AFSA, 2003]</li> <li>• [Glyde, 2004]</li> <li>• [RAW, 2004]</li> <li>• [GAIN GST03]</li> </ul> |   |  |

| 49. | ARCA<br>(Apollo Root Cause Analysis)                 | Stat   | Ret     | 2007 | ARCA is a root cause analysis method that does not aim to find the root cause, but to identify the most effective solution to prevent the primary effect. It is based on 4 basic characteristics: 1. Cause and effect are the same thing; 2. Causes and effects are part of an infinite continuum. 3. Every effect has at least two causes in the form of actions and conditions; 4. An effect exists only if its causes exist at the same point in time and space. Part of the method is creating a RealityChart, which looks for causes of primary effects in actions and conditions, and looks for causes of these causes until a stopping criterion applies. Next, effective solutions are identified by challenging each cause in the Realitychart and checking possible solutions against the best solution criteria.                     | Supported by software   |                         |   |   |   |   |   |   | 6 |         |             | manufacturing, mining, road, rail | x      |        | x      | x          |   | <ul style="list-style-type: none"> <li>• [Ziedelis &amp; Noel, 2011]</li> <li>• [Gano, 2007]</li> <li>• [ARCA web]</li> </ul> |

| 50. | ARIA<br>(Aerodrome Runway Incursion Assessment Tool) | Tab    | Col     | 2006 | ARIA is a computer based assessment that assists in assessing the possibility of runway incursions occurring at an airport, and showing which remedial actions may help to reduce this possibility. The user is presented a list of about 40 characteristics for airports (related to e.g. runway layout, traffic volume, pilot-controller communication, ground vehicles, weather, and potential risk reduction factors such as signs and signals at runway entrance), and selects which of these characteristics apply to the airport under study. Next, the model translates all selected characteristics into a numeric score and weighs and combines them in a formula to generate a runway incursion vulnerability index for the airport.   | The model has been validated against data from 18 European civil airports, which covered a wide range of characteristics.   |                         |   |   |   |   |   | 5 | 6 |         | (airport)   |                                   |        |        |        | x          | <ul style="list-style-type: none"> <li>• [ICAO 9870/AN463]</li> <li>• [ARIA, 2007]</li> <li>• [Van Es, 2006]</li> </ul> |   |
| 51. | ARMS<br>(Aviation Risk Management Solutions)         | Int    | OpR     | 2010 | ARMS defines an overall process for Operational Risk Assessment. This starts with Event Risk Classification (ERC), which is the first review of events in terms of urgency and the need for further investigation. This step also attaches a risk value to each event - which is necessary for creating safety statistics reflecting risk. The next step is data analysis in order to identify current Safety Issues. These Safety Issues are then risk assessed in detail through the Safety Issue Risk Assessment (SIRA). The whole process ensures that any necessary safety actions are identified, creates a Register for following up risks and actions and provides a Safety Performance Monitoring function. SIRA can also be used to make Safety Assessments, which is a requirement of the "Management of Change" element of the SMS. | Developed by the ARMS Working Group. Primary focus is on operational Flight Safety risks, i.e. any risks that could harm the occupants of an aircraft (passengers and crew) |                         |   |   | 3 |   | 5 | 6 |   |         | aviation    | x                                 |        | x      | x      | x          | <ul style="list-style-type: none"> <li>• [ARMS, 2010]</li> </ul>  |   |

| 56. | ASAP<br>(Aviation Safety /<br>Accident Prevention)  | Dat    | Dat     | 1984 | ASAP is a collection of searchable databases, including airworthiness directives, accident/incidents, daily alerts, NTSB recommendations, safety analysis, service difficulty reports (SDRs), and significant SDRs. ASAP comes with software to enhance the tracking, analysis, and reporting of safety related issues and warnings. If an SDR is rated Hazardous or Catastrophic, the responsible engineer investigates the problem, the investigation is tracked in the significant SDR ASAP database, and the investigation is closed with a recommendation.  | ASAP was developed by the FAA Rotorcraft Certification Directorate of the Aircraft Certification Service.   |                         |   |   | 3 |   |   |   |   | 6       |             |        | 8             | aviation              | x       |            |   |  | x |  | <ul style="list-style-type: none"> <li>• [ATN Briefing 2004]</li> <li>• [FAA CFGA]</li> <li>• [SAT-01.1, 1997] (p. 112)</li> </ul>                          |  |
| 57. | ASAP<br>(Aviation Safety<br>Action Program)   | Dat    | Dat     | 1997 | ASAP promotes voluntary reporting of safety issues and events that come to the attention of airline employees, including pilots, flight attendants, repair stations. It includes enforcement-related incentives to encourage employees to voluntarily report safety issues, even though the issues may involve an alleged violation of Title 14 of the FAA Code of Federal Regulations (14 CFR). ASAP safety data, much of which would otherwise be unobtainable, is used to develop corrective actions for identified safety concerns, and to educate the appropriate parties to prevent a reoccurrence of the same type of safety event. | See also ATSAP, which is modelled after ASAP, but which is focused on controllers.  |                         |   |   |   |   |   |   |   | 6       |             |        | 8             | aviation,<br>aircraft | x       |            |   |  | x |  | <ul style="list-style-type: none"> <li>• [ATO SMS Manual v3.0]</li> <li>• [ASAP RPC, 2010]</li> <li>• [ASAP P&amp;G]</li> <li>• [FAA AC 120-66B]</li> </ul> |  |
| 58. | ASAT<br>(Airspace Simulation<br>and Analysis for<br>TERPS (Terminal<br>En-route Radar<br>Procedures)) | FTS    | Col     | 1998 | ASAT is a Monte Carlo simulation tool to estimate e.g. probability of mid-air collision during terminal en route phase. Uses statistical input for Aircraft (flight dynamics, propulsion/performance, wake turbulence, on board avionics), Geographical/Geodetic (digital terrain elevation data, obstacles), Environmental (standards atmosphere, non-standards atmosphere, measured wind and temperature gradients data), Navigation ground systems, Surveillance (PRM, ASR-9, ARSR, TCAS, ADS-B), Human factors (pilot, air traffic control). ASAT can provide answers either in a deterministic or a probabilistic way.                | Developed by ATSI (Air Traffic Simulation, Inc.). PRM = precision runway monitor; ASR = airport surveillance radar; ARSR = air route surveillance radar; TCAS = traffic collision avoidance system; ADS-B = automatic dependent surveillance - broadcast. |                         | 2 |   |   |   | 5 | 6 |   |         |             |        | ATM, aviation | x                     |         | x          | x |  |   | <ul style="list-style-type: none"> <li>• [FAA-AFS-420-86]</li> <li>• [Lankford, 2003]</li> </ul> |   |  |
| 59. | ASCOT<br>(Assessment of<br>Safety Culture in<br>Organisations Team)                                   | Tab    | Org     | 1992 | ASCOT provides organisational self-assessment of safety culture. A review of safety culture involves consideration of all organisations which influence it, including the operating organisation, the regulator and any supporting organisations. For each of these organisations, there are guide questions which should be asked during a review of safety culture and key indicators of an effective safety culture which are used to assess the responses to these questions.  | Qualitative. Developed by IAEA (International Atomic Energy Agency).  |                         |   |   |   |   |   |   |   |         |             |        | 7             | 8                     | nuclear |            |   |  |   | x  |   | <ul style="list-style-type: none"> <li>• [Kennedy &amp; Kirwan, 1998]</li> </ul> |

| 60. | ASEP<br>(Accident Sequence Evaluation Programme)              | Tab    | HRA          | 1987 | Abbreviated and slightly modified version of THERP. ASEP comprises pre-accident screening with nominal human reliability analysis, and post-accident screening and nominal human reliability analysis facilities. Consists of four procedures: Pre-accident tasks, Post-accident tasks, Screening human reliability analysis, Nominal human reliability analysis.  | Nuclear specific tool, developed by A.D. Swain. ASEP provides a shorter route to human reliability analysis than THERP by requiring less training to use the tool, less expertise for screening estimates, and less time to complete the analysis. Is often used as screening method to identify human actions that have to be assessed in more detail using THERP. However, is more conservative. |                         |   |   |   |   | 5 |   |   |         |             |        | nuclear                |        |        | x          |   |   |  | <ul style="list-style-type: none"> <li>[HIFA Data]</li> <li>[Kirwan, 1994]</li> <li>[Kirwan &amp; Kennedy &amp; Hamblen]</li> <li>[Straeter, 2000]</li> <li>[Straeter, 2001]</li> </ul> |
| 61. | ASHRAM<br>(Aviation Safety Human Reliability Analysis Method) | Step   | HRA<br>, Ret | 2000 | ASHRAM allows aviation researchers to analyze aviation accidents and incidents that involve human errors in ways that account for the operational context, crew expectations, training, airframe-related human-system interfaces, crew resource management, and generic human-error mechanisms. It examines the airframe and airspace situational factors, pilot performance-shaping factors, and error mechanisms identified by cognitive psychology to explain and model the overt and covert events leading up to an unsafe act. The ASHRAM cognitive model uses three cognitive functions: environmental perception, reasoning and decision-making, and action.                    | ASHRAM is a second-generation human reliability analysis developed by the Nuclear Regulatory Commission's Sandia National Laboratories. Based on ATHEANA, but adapted for aviation purposes.   |                         |   |   |   |   |   |   |   |         |             |        | (aviation)             |        |        |            | x |   |  | <ul style="list-style-type: none"> <li>[Fitzgerald, 2007]</li> </ul>  |
| 62. | ASIAS<br>(Aviation Safety Information Analysis and Sharing)   | Dat    | Dat          | 2007 | Primary objective is to provide a U.S. national resource for use in discovering common, systemic safety problems that span multiple airlines, fleets and regions of the global air transportation system. ASIAS leverages internal FAA data, de-identified airline safety data and other government and publicly available data sources. It fuses these data sources in order to proactively identify trends in the National Airspace System (NAS) and to assess the impact of changes in the aviation operating environment. Safety information discovered through ASIAS analytic activities is used across the industry to drive improvements and support Safety Management Systems. | Created by FAA. ASIAS gathers data from over 73 U.S. commercial operators. Its focus is currently on the integration of commercial aviation data, but future plans include the expansion of ASIAS to other sectors of the air transportation system. Former name is NASDAC Database (National Aviation Safety Data Analysis Center Database).  |                         |   |   | 3 |   | 5 |   |   |         |             |        | aviation, ATM, airport | x      | x      | x          | x | x |  | <ul style="list-style-type: none"> <li>[ASIAS portal]</li> <li>[Randolph, 2009]</li> <li>[ASIAS refs]</li> <li>[Hadjimichael et al]</li> <li>[Basehore, 2011]</li> </ul>                |

| 63. | ASMS<br>(Aviation Safety Monitoring System)   | Dat    | Dat,<br>Val | 1991 | ASMS is a relational database that links information on aviation document holders with safety failures (occurrences and non-compliances) and tracks corrective actions. It is fully integrated with CAA's management information system and contains tools for creating and maintaining a database, customising and creating occurrence reports, tracking safety investigations, analysing data, and tracking corrective actions. Risk management is facilitated through the use of severity and likelihood codes. Automated Occurrence Report forms provide assistance in entering data and provide an audit trail of changes made. Investigation reports support full multimedia, including pictures. | Purpose: to provide the New Zealand aviation community with safety information as determined from accidents and incidents. It is also used to track corrective actions against non-compliances that are detected during proactive surveillance. It was commissioned in 1991. Ref. [GAIN GST03] refers to AQD as a clone of ASMS and states that AQD and ASMS are compatible in the sense that external organisations are able to gather their own occurrence data, track their own audit corrective actions, analyse the data and report their safety performance to CAA via an electronic interface. |                         |   |   |   |   |   |   |   |         | 8           | aviation | x      |        | x      | x          |  |   | <ul style="list-style-type: none"> <li>• [GAIN ATM, 2003]</li> <li>• [GAIN GST03]</li> </ul> |
| 64. | ASMT<br>(Automatic Safety Monitoring Tool)  | Dat    | Dat,<br>HzI | 2000 | ASMT provides an automatic monitoring facility for safety related occurrences based on operational data. It detects and categorises each occurrence for assessment by trained operational experts. The tool will help determine causes and assist in the evolution of local procedures, airspace design, equipment and techniques. ASMT collects proximity-related occurrences. It will begin collecting ACAS occurrences through Mode-S stations, altitude deviations, runway incursions, airspace penetrations, and route deviations.   | ASMT was developed by the Eurocontrol Experimental Centre (EEC), in co-operation with the Maastricht Upper Airspace Centre, for pilot operational use in 2000. It is also being used as part of the real time ATM simulation facilities at the EEC.   |                         |   |   |   |   |   |   |   |         | 7           | ATM      |        |        |        | x          |  |   | <ul style="list-style-type: none"> <li>• [GAIN ATM, 2003]</li> </ul>                         |

| 65. | ASP<br>(Accident Sequence Precursor)  | Stat   | OpR         | 1979 | ASP is a program containing several models for risk assessment. It identifies nuclear power plant events that are considered precursors to accidents with the potential for severe core damage and uses risk assessment methodologies to determine the quantitative significance of the events. ASP models contain event trees that model the plant response to a selected set of initiating events. When a precursor to be analysed involves one of these initiating events, an initiating event assessment is performed.  | Established by the NRC (Nuclear Regulatory Commission) in 1979 in response to the Risk Assessment Review Group report. In 1994, INEEL (Idaho National Engineering and Environmental Laboratory) started the development for US NRC of a Human Reliability Analysis methodology as part of ASP.  |                         |   |   |   | 4 | 5 |   |   |         |             | nuclear  | x      |        | x      |            |  | <ul style="list-style-type: none"> <li>• [HRA Washington, 2001]</li> <li>• [NRC-status, 1999]</li> <li>• [NSC-ANSTO, 2002]</li> </ul> |  |
| 66. | AsPeCSS<br>(Assessment methodology for forward looking integrated Pedestrian, and further extension to Cyclists Safety Systems) | Step   | HzA         | 2014 | AsPeCSS aims at assessing impact and cost of pedestrian injury due to collisions with road vehicles equipped with safety systems, such as automated emergency braking systems, pedestrian forward collision warning systems. The method includes various test scenarios of pedestrian dummies crossing the road in front of vehicles, measuring speed reduction, and converting dummy pedestrian responses into injury risk and casualty cost. Driver models can also be included.  |   |                         |   |   |   | 4 | 5 |   |   |         |             | road     | x      | x      |        |            |  | <ul style="list-style-type: none"> <li>• [Lubbe &amp; Kullgren, 2015]</li> </ul>  |  |

| 67. | ASRM<br>(Aviation Safety Risk Model)                   | Stat   | OpR     | 1999          | The ASRM is a decision support system aimed to predict the impacts of new safety technologies/ interventions upon aviation accident rate. First the interactions of causal factors are modelled. Next, Bayesian probability and decision theory are used to quantify the accident causal models and to evaluate the possible impacts of new interventions. Each such model is a BBN, and the models are combined into a Hierarchical BBN, i.e. a HBN. The entire process is largely based on expert judgments. ASRM uncertainty and sensitivity analyses is supported by a tool named BN-USA (Bayesian Network-Uncertainty and Sensitivity Analyses).  | ASRM was originally developed for use by US Naval Aviation, but has since been used more widely within the aviation industry. It makes use of HFACS. ASRM is being enhanced and further developed by the NASA Aviation Safety Program Office to evaluate the projected impact upon system risk reduction of multiple new technology insertions/ interventions into the National Airspace System. |                         |   |   |   | 4 | 5 |   |   |         |             |        | aviation      | x      |        |            |   |  | <ul style="list-style-type: none"> <li>• [Luxhøj, 2002]</li> <li>• [Cranfield, 2005]</li> <li>• [Luxhøj, 2005]</li> <li>• [Luxhøj &amp; Coit, 2005]</li> <li>• [Luxhøj &amp; Oztekin, 2005]</li> </ul> |
| 68. | ASRS<br>(Aviation Safety Reporting System)             | Dat    | Dat     | 1975          | The ASRS receives, processes and analyses voluntarily submitted incident reports from pilots, air traffic controllers, and others. Reports submitted to ASRS describe both unsafe occurrences and hazardous situations. ASRS's particular concern is the quality of human performance in the aviation system. Individuals involved in aviation operations (pilots, crew members, ground personnel, etc.) can submit reports to the ASRS when they are involved in or observe a situation that they believe compromised safety. These reports are voluntary and submitted at the discretion of the individual. Teams of experienced pilots and air traffic controllers analyse each report and identify any aviation hazards. | The ASRS was established in 1975 under a memorandum of agreement between FAA and NASA. Datamining tool: QUORUM Perilog   |                         |   |   | 3 |   |   |   |   |         |             | 8      | aviation, ATM | x      |        | x          | x   | x  | <ul style="list-style-type: none"> <li>• [ASRS web]</li> <li>• [GAIN ATM, 2003]</li> <li>• [FAA HFW]</li> </ul>  |
| 69. | Assertions and plausibility checks                     | Step   | SwD     | 1976 or older | Software Testing technique. Aim is to produce code whose intermediate results are continuously checked during execution. An assertion is a predicate (a true-false statement) placed in a program to indicate that the developer thinks that the predicate is always true at that place. When an assertion failure occurs, the programmer is notified of the problem. In case of incorrect results a safety measure is taken.  | Applicable if no complete test or analysis is feasible. Related to self-testing and capability checking. Tools available. See also Software Testing.   |                         |   |   |   |   |   |   | 7 |         | software    |        | x             |        |        |            |   | <ul style="list-style-type: none"> <li>• [Bishop, 1990]</li> </ul> |  |
| 70. | ASSET<br>(Assessment of Safety Significant Event Team) | Stat   | Ret     | 1991          | In ASSET analysis, the event is broken up into logically connected occurrences which can be attributed to a single failure of either people, procedures or equipment, and the direct cause and root causes of each occurrence are identified to determine the corrective actions which will eliminate the direct cause and root causes. From a narrative of the event, the chronological order of occurrences is identified, which are represented by a logic tree in chronological order. For each occurrence analysed, corrective actions are suggested to eliminate the latent weakness identified, with special attention to prevention of repeated failures.  | Developed by IAEA for investigating events of high significance with related managerial and organisational issues. Root cause analysis. No longer supported by IAEA, replaced by PROSPER (2000).   |                         |   |   |   |   | 6 |   |   | 8       | nuclear     | x      |               | x      | x      | x          | <ul style="list-style-type: none"> <li>• [Ziedelis &amp; Noel, 2011]</li> </ul> |  |  |

| 71. | ATCS PMD (Air Traffic Control Specialist Performance Measurement Database) | Dat    | Dat      | 1999 | This database aims at selecting appropriate performance measures that can be used for evaluation of FAA NAS (National Airspace System) operations concepts, procedures, and new equipment. This database is intended to facilitate measurement of the impact of new concepts on controller performance. Using standard database techniques, a researcher can search the database to select measures appropriate to the experimental questions under study. With the selection of a particular measure(s), the database also provides citations for the primary source of the measure and additional references for further information. Having a set of measures with standardised parameters will increase the reliability of results across experiments, and enable comparisons of results across evaluations. | Provides a compilation of techniques that have been proven effective for use in human factor research related to air traffic control. Developed by FAA in 1999.  |                         | 2 |   |   |   |   |   |   | 7       |             |                    |        |        |        |            |  | <ul style="list-style-type: none"> <li>[FAA HFW]</li> <li>[ATCSPMD]</li> <li>[Hadley, 1999]</li> </ul>        |
| 72. | ATHEANA (A Technique for Human Error Analysis)                             | Step   | HRA, Ret | 1996 | Aim is to analyse operational experience and understand the contextual causes of errors, and then to identify significant errors not typically included in PSAs for nuclear power plants, e.g. errors of commission. Key human failure events and associated procedures etc. are identified from the PSA, and unsafe acts are then identified that could affect or cause these events. Associated error-forcing conditions are then identified that could explain why such unsafe acts could occur. The important point is that these forcing conditions are based on the system being assessed, i.e. the real context that is the focus of the assessment.  | Developed by NRC (Nuclear Regulatory Commission). Currently the method relies on operational experience and expert judgement. It is the intention of the authors to produce guidance material on the technical basis of the model. Such material could reduce the reliance on expert judgement and increase the auditability of the technique. Goes beyond THERP in its capability to account for and predict human errors, by examining cognitive processes. See also ASHRAM. |                         |   |   |   |   |   |   |   |         | 8           | nuclear            |        |        |        | x          |  | <ul style="list-style-type: none"> <li>[Kirwan, Part 1, 1998]</li> <li>[Ziedelis &amp; Noel, 2011]</li> </ul> |
| 73. | ATLAS  | Int    | Task     | 1996 | ATLAS is a performance modelling software package designed to support Human Factors Integration studies from an early stage in system development. It can be applied to predict and assess operator performance in critical operating scenarios. It combines a graphically-based task analysis with a database, aiming at maximizing the value of task analysis data. The analysis data structure was based on GOMS. The task data can be viewed and exported in various ways.   | Developed by Human Engineering Limited (UK). Supports a variety of conventional task analysis methods (including hierarchical task analysis (HTA), timeline analysis (TLA) and tabular task analysis (TTA)) and incorporates more than 60 human performance, workload, and human reliability algorithms.   |                         | 2 |   |   |   |   |   |   |         | 8           | ATM, rail, oil&gas |        |        |        | x          |  | <ul style="list-style-type: none"> <li>[Hamilton, 2000]</li> <li>[FAA HFW]</li> </ul>                         |

| 82. | B&UA (Bias and Uncertainty Assessment)       | Math   | Val     | 2002          | Aim is to get detailed insight into the effect of all differences between a model (that is used in a safety risk assessment) and reality. The technique aims to assess all differences on their bias and uncertainty effect on safety risk, and to combine the results to get an estimate of 'true risk' and a credibility interval for 'true risk'. In addition, it aims to identify directions for model improvement as well as directions for safety design improvement and safety design requirements, based on those differences that have the highest effect on bias and/or uncertainty.  | Two categories of uncertainty are: aleatory (reflecting the inherent randomness of processes) and epistemic uncertainty (reflecting restrictions in the state-of-knowledge used for the development of the model). B&UA is an important step in Verification and Validation of model-based safety risk assessment. |                         |   |   |   |   |   | 5 | 6 |         |   |          | ATM      | x      | x      | x          | x  | x  | <ul style="list-style-type: none"> <li>• [Everdij et al, 2006a]</li> <li>• [Everdij &amp; Blom, 2002]</li> <li>• [Everdij &amp; Blom, 2004]</li> <li>• [Nurdin, 2002]</li> </ul> |
| 83. | Back-to-back testing                         | Step   | SwD     | 1986 or older | Software Testing technique. Aim is to detect failures by comparing the output of two or more programs implemented to the same specification. Also known as Comparison Testing.  | Useful if two or more programs are to be produced as part of the normal development process. See also Software Testing.  |                         |   |   |   |   |   |   |   |         | 7                                       |          | software |        | x      |            |  |  | <ul style="list-style-type: none"> <li>• [Bishop, 1990]</li> </ul>   |
| 84. | Backward Recovery or Backward Error Recovery | Step   | Des     | 1989 or older | Back-up to a previous state that was known to be correct; then no (or little) knowledge of the error is needed. The Backward Recovery approach tends to be more generally applicable than the forward recovery approach - errors are often unpredictable, as are their effects.   | Software architecture phase. See also Forward Recovery.  |                         |   |   |   |   |   |   | 6 |         |   | software |          | x      |        |            |  | <ul style="list-style-type: none"> <li>• [EN 50128, 1996]</li> <li>• [Rakowsky]</li> <li>• [SSCS]</li> </ul> |  |
| 85. | Barrier Analysis                             | Stat   | Mit     | 1973          | Barrier analysis is a structured way to consider the events related to a system failure. It suggests that an incident is likely preceded by an uncontrolled transfer of energy and therefore for an incident to occur there needs to be: 1. A person present 2. A source of energy 3. A failed barrier between the two. Barriers are developed and integrated into a system or work process to protect personnel and equipment from unwanted energy flows. Is implemented by identifying energy flow(s) that may be hazardous and then identifying or developing the barriers that must be in place to form damaging equipment, and/or causing system damage, and/or injury. Can also be used to identify unimaginable hazards. | Similar to ETBA (Energy Trace and Barrier Analysis). Barrier analysis is a qualitative tool for systems analysis, safety reviews, and accident analysis. Combines with MORT. Not to be confused with the Barrier Analysis developed by T. Davis (1990), which is used to study behaviour change in e.g. children.  |                         |   |   | 3 |   |   | 6 |   |         | chemical, nuclear, police, road, (rail) | x        |          |        |        |            | <ul style="list-style-type: none"> <li>• [FAA00]</li> <li>• [Kirwan &amp; Ainsworth, 1992]</li> <li>• [ΣΣ93, ΣΣ97]</li> <li>• [FAA HFW]</li> </ul> |  |  |

| 87. | BBN<br>(Bayesian Belief<br>Networks)                       | Stat   | Mod     | 1950 | BBN (also known as Bayesian networks, Bayes networks, Probabilistic cause-effect models and Causal probabilistic networks), are probabilistic networks derived from Bayes theorem, which allows the inference of a future event based on prior evidence. A BBN consists of a graphical structure, encoding a domain's variables, the qualitative relationships between them, and a quantitative part, encoding probabilities over the variable. A BBN can be extended to include decisions as well as value or utility functions, which describe the preferences of the decision-maker. BBN provide a method to represent relationships between propositions or variables, even if the relationships involve uncertainty, unpredictability or imprecision. By adding decision variables (things that can be controlled), and utility variables (things we want to optimise) to the relationships of a belief network, a decision network (also known as an influence diagram) is formed. This can be used to find optimal decisions, control systems, or plans. | Bayesian belief networks are based on the work of the mathematician and theologian Rev. Thomas Bayes (1702-1761), who worked with conditional probability theory in the late 1700s to discover a basic law of probability, which was then called Bayes' rule: $p(A   B) = (p(A) * p(B   A)) / p(B)$ . The term Bayesian came in use around 1950. The term "Bayesian networks" was coined by Judea Pearl (1985). Tools available, e.g. SERENE (SafEty and Risk Evaluation using bayesian NEts), see [GAIN ATM, 2003]; HUGIN. | 92. | Bond-Graphs                                      | Dyn    | Mod     | 1961                | A Bond graph is a modelling approach using graphical representation of a physical dynamic system. The "bonds" link together "single port", "double port" and "multi port" elements. Each bond represents the instantaneous bi-directional flow of physical energy (dE/dt) or power. The energy exchange includes mechanical, electrical, hydraulic energy. The flow in each bond is denoted by a pair of variables called 'power variables' whose product is the instantaneous power of the bond. The power variables are broken into two types: "effort" and "flow". Effort multiplied by flow produces power. | Developed by Henry Paynter, MIT. The term "bond graph" comes from the notion that many of these graphs look like the bonds in chemistry. If the dynamics of the physical system to be modelled operate on widely varying time scales, fast continuous-time behaviours can be modelled as instantaneous phenomena by using a hybrid bond graph.  |                         |   |   | 2 |   | 4 |   |   |         |             |        |        |        |        |            |  |  | <ul style="list-style-type: none"> <li>• [Broenink, 1999]</li> <li>• [Gero &amp; Tsai, 2004]</li> </ul>  |
| 93. | Boundary value analysis                          | Step   | SwD     | 1992 probably older | Software Testing technique. Boundary value analysis is a software testing technique in which tests are designed to include representatives of boundary values, which are values on the edge of an equivalence partition or at the smallest value on either side of an edge. The values could be either input or output ranges of a software component. Since these boundaries are common locations for errors that result in software faults they are frequently exercised in test cases.   | Boundary-value testing of individual software components or entire software systems is an accepted technique in the software industry. See also Software Testing.   |                         |   |   |   |   |   |   |   |         |             |        |        |        |        |            |  |  | <ul style="list-style-type: none"> <li>• [EN 50128, 1996]</li> <li>• [Jones et al, 2001]</li> <li>• [Rakowsky]</li> <li>• [Sparkman, 1992]</li> </ul>  |
| 94. | Bow-Tie Analysis                                 | Stat   | Mit     | 1999                | Aim is to enhance communication between safety experts (who construct a Bow-Tie diagram) and operational experts (who identify hazard mitigating measures using the Bow-Tie diagram). The knot of the Bow-Tie represents a releasing event or a hazard. The left-hand side wing shows threats and Pro-active measures, which improve the chances to avoid entering the hazard; the right-hand side wing shows consequences and Re-active measures to improve the chances to escape from the hazard prior to its escalation.   | Developed by Royal Dutch Shell. The Bow-Tie Diagram has evolved over the past decades from the Cause Consequence Diagram of the 1970s and the Barrier Diagram of the mid 1980s. It has been most often used in chemical and petrochemical industries. The approach has been popularised at EU Safety Case Conference, 1999, as a structured approach for risk analysis within safety cases where quantification is not possible or desirable. See also CCDM or CCA. |                         |   |   |   |   |   |   |   | 6       |             |        |        |        |        |            |  |  | <ul style="list-style-type: none"> <li>• [Bishop, 1990]</li> <li>• [Villemeur, 1991]</li> <li>• [Rademakers et al, 1992]</li> <li>• [EN 50128, 1996]</li> <li>• [Edwards, 1999]</li> <li>• [Zuijderdijn, 1999]</li> <li>• [Trbojevic &amp; Carr, 1999]</li> <li>• [Blom &amp; Everdij &amp; Daams, 1999]</li> <li>• [DNV-HSE, 2001]</li> <li>• [Petrolekas &amp; Haritopoulos, 2001]</li> <li>• [FAA HFV]</li> </ul> |
| 95. | Bow-Tie Analysis using Fault Tree and Event Tree | Stat   | HZA     | 2002                | A method for cause-consequence analysis of a hazard or critical event. The left-hand-side of the Bow-Tie is formed by a Fault Tree, which models how the hazard is caused by combinations of primary events. The right-hand-side of the Bow-Tie is formed by an Event Tree, which models the consequences of the hazard.  | This type of bow-tie is also known as Cause-Consequence Diagram (CCD). See also CCDM or CCA.  |                         |   |   |   |   | 4 |   |   |         |             |        |        |        |        |            |  |  | <ul style="list-style-type: none"> <li>• [EN 50128, 1996]</li> <li>• [EHQ-PSSA, 2002]</li> <li>• [Harms-Ringdahl, 2013]</li> </ul>   |

| 96. | BPA<br>(Bent Pin Analysis)  | Step   | HwD     | 1965          | BPA is an analysis technique for identifying hazards caused by bent pins within cable connectors. It evaluates the effects should connectors short as a result of bent pins and mating or demating of connectors. BPA generally only considers and evaluates the effect of a single bent pin contacting another pin within its radius or with the connector case. BPA does not consider two pins bending and making contact with each other or with a third pin, except in the case of high-consequence circuits.  | Developed by The Boeing Company circa 1965, on the Minuteman program. Any connector has the potential for bent pins to occur. Connector shorts can cause system malfunctions, anomalous operations, and other risks. Combines with and is similar to CFMA. Applicable during maintenance operations. Sometimes referred to as a subset of FMEA. |                         |   |   | 3 |   | 5 |   |   |         |             |                               | defence | x      |        |            |   |   |   | <ul style="list-style-type: none"> <li>• [ΣΣ93, ΣΣ97]</li> <li>• [FAA00]</li> <li>• [Ericson, 2005]</li> </ul> |
| 97. | Brahms<br>(Business Redesign Agent-based Holistic Modelling System) | Dyn    | Mod     | 1997          | Agent-based simulation tool for modelling the activities of groups in different locations. The typical simulation can be organized into 7 component models: 1. Agent model: the groups of people, individuals (agents), and their interrelationships; 2. Activity model: the activities that can be performed by agents and objects; 3. Communication model: the communication among agents and between agents and objects; 4. Timing model: the temporal constraints and relationships between activities; 5. Knowledge model: the initial beliefs and thought frames of agents and objects; 6. Object model: the objects in the world used as resources by agents or used to track information flow; 7. Geography model: the specification of geographical areas and potential paths in which agents and objects perform their activities. | Developed 1992-1997 by B. Clancey, D. Torok, M. Sierhuis, and R. van Hoof, at NYNEX Science and Technology; after 1997 development was continued by NASA ARC. Can be used qualitatively or quantitatively.  |                         |   |   |   | 4 | 5 |   |   |         |             | management, healthcare, space |         |        |        | x          | x | x |   | <ul style="list-style-type: none"> <li>• [Morrison, 2003]</li> </ul>   |
| 98. | Brainstorming   | Gen    | Dat     | 1953 or older | A group of experts sit together and produce ideas. Several approaches are known, e.g. at one side of the spectrum the experts write down ideas privately, and then gather these ideas, and at the other side of the spectrum, the expert openly generate ideas in a group.   | The term Brainstorming was popularised by A.F. Osborn in 1953. | 101. | Bug-counting model  | Step   | SwD       | 1983 or older | Model that tends to estimate the number of remaining errors in a software product, and hence the minimum time to correct these bugs.  | Not considered very reliable, but can be used for general opinion and for comparison of software modules. See also Musa Models. See also Jelinski-Moranda models.  |                         |   |   | 3 |   |   |   |   |         |             | software   |        | x      |        |            |   |   | <ul style="list-style-type: none"> <li>[Bishop, 1990]</li> </ul>  |
| 102. | C3TRACE (Command, Control, and Communication-Techniques for Reliable Assessment of Concept Execution) | Step   | Org, Task | 2003          | C3TRACE provides an environment that can be used to evaluate the effects of different personnel configurations and information technology on human performance as well as on overall system performance. This tool provides the capability to represent any organisation, the people assigned to that organisation, the tasks and functions they will perform, and a communications pattern within and outside the organisation, all as a function of information flow and information quality.   |  |                         |   |   | 4 |   |   |   |   |         | 8           | defence  |        |        |        | x          |   | x | <ul style="list-style-type: none"> <li>[Kilduff et al, 2005]</li> <li>[FAA HFW]</li> <li>[Alley, 2005]</li> </ul> |
| 103. | CAAM (Continued Airworthiness Assessment Methodologies)   | Step   | HwD       | 2002          | CAAM is an aircraft engine reliability and failure data analysis tool used to identify and prioritize unsafe conditions. Steps are: a) Identify potential unsafe condition; b) Estimate the number of aircraft exposed; c) Estimate the uncorrected risk factor (i.e. the expected number of events if no action is taken to address the condition) and risk per flight, by means of analytical techniques such as root cause problem assessments; d) Estimate effects (potential risk reduction) of candidate mitigating actions; e) Implement and monitor corrective action plan. Five CAAM hazard levels are used, ranging from level 5 (catastrophic consequences) to level 1 (minor consequences). Levels 3, 4 and 5 represent the greatest area of safety concern, and a hazard ratio is established for these occurrences, i.e. the conditional probability that a particular powerplant installation failure mode will result in an event of such hazard level. | The CAAM process was developed by FAA in 1994-2002, and was based on a 1993 study by AIA (Aerospace Industries Association) aimed at addressing safety related problems occurring on commercial aircraft engines. CAAM is reactive to incidents, in the sense that it depends on data from incidents and other reported problems, and it cannot react to situations for which operational data are not available. In addition, CAAM is proactive to accidents, in the sense that it uses data from minor abnormalities to predict more serious problems. |                         | 2 | 3 | 4 | 5 | 6 | 7 |   |         |             | aircraft   | x      |        |        |            |   |   | <ul style="list-style-type: none"> <li>[FAA AC 39-8, 2003]</li> <li>[FAA AC 33.4-2, 2001]</li> </ul>              |
| 104. | CADA (Critical Action and Decision Approach)  | Tab    | HRA, Task | 1988          | CADA is a technique for systematic examination of decision-making tasks. It utilizes checklists to classify and examine decision errors and to assess their likelihood. Psychologically-based tool. Model-based incident analysis / HRA.  | Apparently not in current use or else used rarely. Developed from Murphy diagrams and SRK.   |                         |   |   |   |   | 5 |   |   |         |             | nuclear  |        |        |        | x          |   |   | <ul style="list-style-type: none"> <li>[Kirwan, Part 1, 1998]</li> </ul>  |

| 105. | CADORS<br>(Civil Aviation Daily Occurrence Reporting System)                                   | Dat    | Dat      | 1996        | CADORS is a Canadian national data reporting system that is used to collect timely information concerning operational occurrences within the Canadian National Civil Air Transportation System and is used in the early identification of potential aviation hazards and system deficiencies. Under the Aeronautics Act, there is a mandatory requirement for ATS certificate holders to report items listed in the CADORS Manual. CADORS reports are collected from a number of sources, but NAV CANADA supplies close to 80% of all reports. Other information providers include Transportation Safety Board, airports, police forces, public, etc. CADORS captures a wide scope of safety related events including ATC operating irregularities; communication, navigation, surveillance, and other air traffic systems failures; controlled airspace violations; etc. Included in the collection are occurrences related to aircraft, aerodromes, security (e.g. bomb threats, strike actions) and environment (e.g. fuel spills) | In 2001, CADORS consisted of 36,000 safety reports of aviation occurrences.   |                         |   |   | 3 |   |   |   |   |         |             | 8  | aviation, ATM, aircraft, airport, security, environment | x      |        | x          | x |  |   | • [GAIN ATM, 2003] |
| 106. | CAE Diagrams<br>(Conclusion, Analysis, Evidence Diagrams or Claims-Argument-Evidence Diagrams) | Stat   | Ret      | 1996        | CAE Diagrams are used to structure a safety case of an accident. They provide a road-map of the evidence and analysis of an accident and encourage analysts to consider the evidence that supports particular lines of argument. CAE diagrams are graphs. The roots represent individual conclusions/claims from an accident report. Lines of analysis/arguments that are connected to items of evidence support these. Each item of evidence either weakens or strengthens a line of analysis/argument. Lines of analysis/argument may also strengthen or weaken the conclusion/claim at the root of the tree.   | Conclusion Analysis Evidence diagrams were developed by Chris Johnson (Univ. Glasgow). The consultancy firm Adelard developed a version named Claims-Argument-Evidence diagrams. Link with GSN. CAE is different to GSN; it uses different shapes and approach, but similar concepts. It is an approach to 'graphical argumentation'. |                         |   |   | 4 |   |   |   |   |         |             | maritime, healthcare, management, aircraft | x   |        |        | x          |   |  | • [Johnson, 1999]<br>• [Johnson, 2003]<br>• [Johnson, 2003a]<br>• [UK CAA SRG, 2010]<br>• [Bishop & Bloomfield, 1998]<br>• [Bloomfield & Wetherilt, 2012]<br>• [Greenwell, 2005]        |                    |
| 107. | CAHR<br>(Connectionism Assessment of Human Reliability)  | Tab    | HRA, Ret | 1992 - 1998 | The Database-System CAHR is a twofold tool aiming at retrospective event analysis and prospective assessment of human actions. It is implemented as a tool for analysing operational disturbances, which are caused by inadequate human actions or organisational factors using Microsoft ACCESS. Retrospectively, CAHR contains a generic framework for the event analysis supported by a knowledge base of taxonomies and causes that is extendable by the description of further events. The knowledge-base contains information about the system-state and the tasks as well as for error opportunities and influencing factors (Performance Shaping Factors). Prospectively it aims to provide qualitative and quantitative data for assessing human reliability.  | The term Connectionism was coined by modelling human cognition on the basis of artificial intelligence models. It refers to the idea that human performance is affected by the interrelation of multiple conditions and factors rather than singular ones that may be treated isolated. Developed 1992-1998. See also CAHR-VA.        |                         |   |   |   | 5 |   |   |   |         |             | nuclear, maritime, manufacturing, rail     |   |        | x      | x          | x |  | • [HRA Washington, 2001]<br>• [Straeter et al, 1999]<br>• [Apostolakis et al, 2004]<br>• [Straeter, 2006a]<br>• [Straeter, 2000]<br>• [Ghamdi & Straeter, 2011]<br>• [Loer et al, 2011] |                    |

| 109. | CAIR<br>(Confidential Aviation Incident Reporting)                               | Dat    | Dat     | 1988          | CAIR aims to gather data that would not be reported under a mandatory system. It covers flight crews, maintenance workers, passengers, and air traffic service officers. The program is designed to capture information, no matter how minor the incident. While confidentiality is maintained, the report must not be anonymous or contain unverifiable information. The ATSB supplement in the 'Flight Safety Australia' magazine is the primary method of publishing a report and obtaining feedback on CAIR issues. Publication of selected CAIR reports on the Internet is planned. Air safety investigations are performed by ATSB independent of the Civil Aviation Safety Authority (CASA) (the regulator) and AirServices Australia (the air traffic service provider). The ATSB has no power to implement its recommendations. | CAIR was instituted by the Australian Transport Safety Bureau (ATSB) in 1988 as a supplement to their mandatory reporting system, the Air Safety Incident Report (ASIR). The program's focus is on systems, procedures and equipment, rather than on individuals. In 2004, CAIR was replaced by the Aviation Self Reporting (ASR) system, which was introduced in 1988. Several other countries have an analogue to CAIR, such as Singapore (SINCAIR), Samoa (SACAIR), Korea (KAIRS), UK (CHIRP), USA (ASRS). The Australian CAIR was modelled directly on ASRS. |                         |   |   |   |   |   |   |   |         |             |        | 8      | aviation, ATM, aircraft, airport, security | x      |            |  | x | x |   |  | <ul style="list-style-type: none"> <li>• [GAIN ATM, 2003]</li> <li>• [Salmon et al., 2005]</li> </ul> |
| 110. | CAMEO/TAT<br>(Cognitive Action Modelling of Erring Operator/Task Analysis Tool ) | RTS    | Task    | 1991          | Simulation approach acting as a task analysis tool, primarily to evaluating task design, but also for potential use in Human Reliability Assessment. It allows designers to ensure that operators can carry out tasks. Performance Shaping Factors used in the approach include task load, complexity, time pressure, opportunistic change of task order, multiple task environments, negative feedback from previously made decisions or actions, operator's policies and traits, etc.  | This approach is relatively rare in Human Error Identification, where more usually either an 'average' operator is considered, or a conservatively worse than average one is conceptualised.   |                         |   | 2 | 3 |   |   |   |   |         |             |        |        | (nuclear)                                  |        |            |  | x | x |   |  | <ul style="list-style-type: none"> <li>• [Fujita, 1994]</li> <li>• [Kirwan, Part 1, 1998]</li> </ul>  |
| 111. | CANSO Common Safety Method   | Int    | OpR     | 2014          | This standard aims to be a common framework on safety risk evaluation and assessment for air navigation service providers, applying to ground-based functional changes to air traffic management. Steps are: a. functional system definition (objective, elements, boundary, environment, safety measures); b. risk analysis (hazard identification and risk acceptability); c. risk evaluation (i.e. comparison with risk acceptance criteria); and d. safety requirements (i.e. safety measures to be implemented to reduce risk, and demonstration of compliance). For the risk acceptability step, three methods can be used: 1) application of codes of practice; 2) comparison with similar reference functional system; 3) explicit estimation of frequency and severity of hazardous scenarios.                                  | Framework; the practitioner has the freedom to choose how to conduct all steps. CANSO is the Civil Air Navigation Services Organisation, which has 80 full members and 79 associate members (as of 2014).  | 1                       | 2 | 3 | 4 | 5 | 6 |   |   |         |             |        |        | (ATM)                                      | x      |            |  | x | x |   |  | <ul style="list-style-type: none"> <li>• [CANSO, 2014]</li> </ul>                                     |
| 112. | CAP<br>(Comprehensive Assessment Plan)   | Tab    | Val     | 1988 or older | The CAP is a tool for planning, documenting, and tracking Design Assessments (DA) and Performance Assessments (PA). The CAP is developed during initial certification or at an annual planning meeting. The CAP documents the planned assessments at the system element level. The principal inspector uses the CAP to adjust priorities and due dates of assessments, and to record the reasons for making adjustments.   | Widely applied in education domain.  |                         |   |   |   |   |   |   |   |         |             |        | 7      | social, healthcare, environment, aviation  | x      |            |  |   | x | x |  | <ul style="list-style-type: none"> <li>• [FAA FSIMS, 2009]</li> </ul>                                 |

| 114. | Card Sorting                                       | Min    | HZA     | 1960 | <p>Card Sorting is a technique for discovering the latent structure in an unsorted list of statements or ideas. The investigator writes each statement on a small index card and requests six or more subject matter experts to individually sort these cards into groups or clusters. The results of the individual sorts are then combined and if necessary analyzed statistically. Related techniques are:</p> <ul style="list-style-type: none"> <li>• Affinity Diagrams, which is a brainstorming method that helps to first generate, then organize ideas or concerns into logical groupings. It is used to sort large amounts of complex, or not easily organized data. Existing items and/or new items identified by individuals are written on sticky notes which are sorted into categories as a workshop activity. Can incorporate the representation of the flow of time, in order to describe the conditions under which a task is performed.</li> <li>• Cluster analysis is a collection of statistical methods that is used to organize observed data into meaningful structures or clusters. The measure of the relationship between any two items is that pair's similarity score. Cluster analysis programs can display output in the form of tree diagrams, in which the relationship between each pair of cards is represented graphically by the distance between the origin and the branching of the lines leading to the two clusters. Cluster members share certain properties and thus the resultant classification will provide some insight into a research topic.</li> <li>• Content analysis (1969) is a research tool that uses a set of categorisation procedures for making valid and replicable inferences from data to their context. It is analogous to Card Sorting. Researchers quantify and analyze the presence, meanings and relationships of words and concepts, then make inferences about the messages within the texts. CA is usually carried out as part of an analysis of a large body of data such as user suggestions. Content analysis is conducted in five steps: 1. Coding. 2. Categorizing. 3. Classifying. 4. Comparing. 5. Concluding.</li> <li>• P Sort is a sorting technique where the expert is asked to sort a limited number of domain concepts into a fixed number of categories.</li> <li>• Q Sort is a process whereby a subject models his or her point of view by rank-ordering items into 'piles' along a continuum defined by a certain instruction.</li> </ul> | The affinity diagram was devised by Jiro Kawakita in the 1960s and is sometimes referred to as the Kawakito Jiro (KJ) Method. |                         |   | 2 |   |   | 5 |   |   |         |             | manufacturing | x      |        |        |            | x | x | <ul style="list-style-type: none"> <li>• [Affinity Diagram]</li> <li>• [Cluster Analysis]</li> <li>• [Anderberg, 1973]</li> </ul> |

| 115. | CASE<br>(Controlled Airspace Synthetic Environment)                      | RTS    | Trai    | 1998 | CASE is a training system that models the complete airspace system from gate-to-gate. The CASE simulator is capable of recording every single event that occurs within the scenario that has been defined. In addition to modelling the performance/profiles of any number of aircraft and ground vehicles, CASE is also able to evaluate and analyse events such as congestion, sector loading, the number of times a separation threshold has been violated the number of aircraft controlled by each control station, etc. The core elements are: 1) a Central Processing Suite, 2) up to thirty-five Pilot, Controller (and Supervisor) Operator Workstations, 3) an Exercise Preparation System, and 4) Voice and data communications networks.  | Developed by AMS (Alenia Marconi Systems).   |                         | 2 |   |   |   |   |   |   |         |                    | ATM, defence | x      |        | x      | x          | x |  | • [GAIN ATM, 2003]                               |
| 116. | CAS-HEAR<br>(Computer-Aided System for Human Error Analysis & Reduction) | Stat   | Ret     | 2008 | Method aims at a systematic and thorough analysis of human error in an accident. Steps are: 1) Select critical human errors from the accident sequence. 2) For each of the human subjects who committed the errors, analyse the operator-, task-, environment-, and organisation-related contexts. Rate the degree of influence on the accident on a five-level scale (very low-very high). 3) Identify the error types. 4) Identify error causes. This uses a classification scheme that contains causally linked factors. Causal factors linked to contextual factors rated 'Very high' in Step 2 are selected, and influences are identified by following the causal links. Repeat this process until the root causes of the error are found. 5) Analyse error handling processes, including error detection and recovery 6) Analyse barriers. These can be physical administrative or procedural barriers. 7) Review causal analysis and determine the key causes of the accident. 8) Develop corrective actions. 9) Evaluate corrective actions. | Based on managerial error analysis system HEAR (Human Error Analysis & Reduction), which was developed for use in the Korean railway industry. CAS-HEAR was designed to increase the quality and efficiency of human error analysis using HEAR. Although CAS-HEAR was developed specifically for the railway industry, it is said to be applicable to other industries with minor modifications. |                         |   |   | 4 |   | 6 |   |   | 8       | rail               |              |        |        | x      |            |   |  | • [Ziedelis & Noel, 2011]<br>• [Kim et al, 2008] |

| 118. | CAST<br>(Causal Analysis based on STAMP)        | Step   | Ret     | 2011 | CAST is STAMP-based retrospective analysis of actual accidents and incidents. It takes as input a comprehensive accident report, and proceeds to thoroughly explain why the accident occurred, rather than who is to blame. The CAST methodology follows these steps: 1. Define the system and hazards in the accident. 2. Identify system safety constraints and associated safety requirements. 3. Define system control structure. 4. Estimate the events leading up to the accident. 5. Analyze loss at the physical system level. 6. By ascending and descending throughout the system control, determine the how and why each successive higher level allowed the inadequate control to continue to be erroneous. 7. Evaluate overall coordination and communication contributors to the accident. 8. Determine dynamic changes in the system and the safety control structure relating to the loss and any weakening of the safety over time. 9. Generate Recommendations.  | CAST is based on STAMP and was developed by Nancy Leveson and co-authors. Following STAMP principles, safety is treated as a control problem, rather than as a failure problem; accidents are viewed as the result of inadequate enforcement of constraints on system behavior.   |                         |   |   |   |   |   |   |   |         | 8           | aviation,<br>finance, food,<br>rail, healthcare | x      | x      | x      | x          | x  | • [Leveson, 2011]                          |
| 119. | CAT<br>(Cognitive Analysis Tool)                | Dat    | Mod     | 1992 | CAT is a computerized GOMS technique for soliciting information from experts. CAT allows the user to describe his or her knowledge in an area of expertise by listing the goals, subgoals, and one or more methods for achieving these goals, along with selection rules. These production rules form the basis of GOMS models that can be used to generate detailed predictions of task execution time using a proposed interface. Cognitive aspects of the task may be derived from this method, but the technique itself does not guarantee it.   | Developed by Dr. Kent Williams in 1992. A development based on lessons learned from CAT is referred to as CAT-HCI (CAT for Human Computer Interaction). Link with GOMS.   |                         |   | 2 |   |   |   |   |   |         |             | (navy), (social)                                |        |        | x      | x          | • [FAA HFW]<br>• [Williams et al., 1998] |  |
| 120. | CATS<br>(Causal model for Air Transport safety) | Stat   | Dat     | 2005 | A causal model represents the causes of commercial air transport accidents and the safeguards that are in place to prevent them. The primary process is further subdivided into several flight phases: take-off, en-route and approach and landing. Events occurring between an aircraft's landing and its next flight are not modelled. The numerical estimates derived in the model apply to western-built aircraft, heavier than 5700 kg, maximum take-off weight. The model apportions the probability per flight of an accident over the various scenarios and causes that can lead to the top event. The CATS model architecture includes Event Sequence Diagrams (ESDs), Fault Trees (FTs) and Bayesian Belief Nets (BBNs). ESDs represent the main event sequences that might occur in a typical flight operation and the potential deviations from normal. FTs resolve the events in an ESD into base events. The base events relating to human error are further resolved into causal events, which relate to the base events via probabilistic influence, as captured in a BBN. | CATS arose from the need for a thorough understanding of the causal factors underlying the risks implied by the air transport, so that improvements in safety can be made as effectively as possible. It was developed for the Netherlands Ministry of Transport and Water Management by a consortium including Delft University of Technology, National Aerospace Laboratory NLR, White Queen Safety Strategies, the National Institute for Physical Safety (NIVF), Det Norske Veritas (DNV) and JPSC. The model currently consists of 1365 nodes, 532 functional nodes, representing ESDs and FTs, and 833 probabilistic nodes. |                         |   |   |   |   |   |   |   |         | 8           | aviation  | x      |        |        |            |  | • [Ale et al, 2006]<br>• [Ale et al, 2008] |

| 122. | Causal Networks                                    | Stat   | Mod     | 1940<br>or<br>older | Graph of random quantities, which can be in different states. The nodes are connected by directed arcs which model that one node has influence on another node.   | The idea of using networks to represent interdependencies of events seems to have developed with the systematisation of manufacturing in the early 1900s and has been popular since at least the 1940s. Early applications included switching circuits, logistics planning, decision analysis and general flow charting. In the last few decades causal networks have been widely used in system specification methods such as Petri nets, as well as in schemes for medical and other diagnosis. Since at least the 1960s, causal networks have also been discussed as representations of connections between events in spacetime, particularly in quantum mechanics. |                         |   |   |   |   |   |   |   |         |             |     |     | 4   |            |            |  |  |   |   |  | <ul style="list-style-type: none"> <li>• [Loeve &amp; Moek &amp; Arsenis, 1996]</li> <li>• [Wolfram, 2002]</li> </ul>                               |  |

| 123. | CbC<br>or<br>CbyC<br>(Correctness-by-Construction) | Gen    | Des     | 1992<br>about       | In contrast to 'construction by correction' (i.e., build and debug), CbC seeks to produce a product that is inherently correct. Aim of CbC is to employ constructive means that preclude defects. It is a process for developing high integrity software, aiming at removing defects at the earliest stages. The process almost always uses formal methods to specify behavioural, security and safety properties of the software. The seven key principles of Correctness-by-Construction are: Expect requirements to change; Know why you're testing (debug + verification); Eliminate errors before testing; Write software that is easy to verify; Develop incrementally; Some aspects of software development are just plain hard; Software is not useful by itself. | Developed by Praxis Critical Systems. Correctness-by-Construction is one of the few secure SDLC processes that incorporate formal methods into many development activities. Requirements are specified using Z, and verified. Code is checked by verification software, and is written in Spark, a subset of Ada which can be statically assured.  |                         |   |   |   |   |   |   |   |         |             |     |     |     | 5          | 6          |  |  |   |   |  | <ul style="list-style-type: none"> <li>• [Amey, 2006]</li> <li>• [Leveson, 1995]</li> <li>• [IEC 61508-6, 1998]</li> <li>• [CbC lecture]</li> </ul> |  |

| 124. | CBFTA<br>(Condition-Based<br>Fault Tree Analysis)           | Stat   | HwD         | 2007 | CBFTA is a tool for updating reliability values of a specific system and for calculating the residual life according to the system's monitored conditions. It starts with a known FTA. Condition monitoring methods applied to systems are used to determine updated failure rate values of sensitive components, which are then applied to the FTA. CBFTA recalculates periodically the top event failure rate, thus determining the probability of system failure and the probability of successful system operation.   | CBFTA is for use during the systems operational phase, including maintenance, not just during design.  |                         |   |   |   |   |   |   |   |         | 7           |   | manufacturing | x      |        |            |   |   |  | • [ShalevTiran, 2007] |
| 125. | CBR<br>(Case-Based<br>Reasoning)                            | Min    | Dat,<br>Mit | 1980 | Case-based reasoning aims at using old specific experiences to understand and solve new problems (new cases). A CBR application uses a previous situation similar to the current one to: solve a new problem, meet new demands, explain new situations, critique new solutions, interpret a new situation, or to create an equitable solution to a new problem. CBR generally follows the following process: 1) Retrieve the most similar case (or cases) by comparing the case to a collection or library of previous cases; 2) Reuse the information and knowledge in the retrieved case to propose a solution to the current problem; 3) Revise and adapt the proposed solution if necessary; 4) Retain the parts of this experience likely to be useful for future problem solving. | CBR was developed in the early 1980s at Yale University. A specific approach to CBR applied to the aviation domain has been developed in [Luxhøj, 2005], [Luxhøj & Oztekin, 2005], and is aimed at accident scenario knowledge management. Given an accident scenario, the user answers a given set of questions. These answers are used to retrieve from an accident case library a list of candidate cases (i.e., solution possibilities) with certain relevance factors attached to them. The retrieved cases are ranked with respect to their similarity to the current accident scenario. |                         |   | 3 |   | 5 | 6 |   |   |         |             | aviation,<br>healthcare,<br>ATM,<br>manufacturing,<br>navy, nuclear,<br>food, finance,<br>oil&gas, road,<br>rail,<br>management | x             | x      | x      | x          | x | • [Luxhøj, 2005]<br>• [Luxhøj & Oztekin, 2005]<br>• [Kolodner 1992]<br>• [Aamodt, 1994]<br>• [Bergman, 1998]<br>• [Harrison, 1997]  |  |                       |
| 126. | CCA<br>(Common Cause<br>Analysis)                           | Int    | HZA         | 1974 | Common Cause Analysis will identify common failures or common events that eliminate redundancy in a system, operation, or procedure. Is used to identify sources of common cause failures and effects of components on their neighbours. Is subdivided into three areas of study: Zonal Analysis, Particular Risks Assessment, and Common Mode Analysis.  | Common causes are present in almost any system where there is any commonality, such as human interface, common task, and common designs, anything that has a redundancy, from a part, component, sub-system or system. Related to Root Cause Analysis. CCA is a term mainly used within the aerospace industry. In the nuclear industry, CCA is referred to as Dependent Failure Analysis. According to [Mauri, 2000], common cause failures and cascade failures are specific types of dependent failures; common mode failures are specific types of common cause failures.                  |                         |   | 3 |   | 5 |   |   |   |         |             | aircraft,<br>nuclear, energy  | x             | x      |        |            |   | • [ARP 4754]<br>• [EN 50128, 1996]<br>• [FAA AC431]<br>• [FAA00]<br>• [Mauri, 2000]<br>• [MUFTIS3.2-1, 1996]<br>• [Rakowsky]<br>• [ΣΣ93, ΣΣ97]<br>• [Amberkar et al, 2001]<br>• [DS-00-56, 1999]<br>• [Mauri, 2000]<br>• [Lawrence, 1999]<br>• [Sparkman, 1992]<br>• [Mosley, 1991]<br>• [Browne et al, 2008] |  |                       |

| 127. | CCDM<br>(Cause Consequence Diagram Method)<br>or<br>CCA<br>(Cause Consequence Analysis) | Stat             | Mod     | 1971 | Aim is to model, in diagrammatical form, the sequence of events that can develop in a system as a consequence of combinations of basic events. Cause-Consequence Analysis combines bottom-up and top-down analysis techniques of Binary Decision Diagrams (BDD) and Fault Trees. The result is the development of potential accident scenarios.   | Developed at Risø laboratories (Denmark) in the 1970's to aid in the reliability analysis of nuclear power plants in Scandinavian countries. For assessment of hardware systems; more difficult to use in software systems. Related to BDD, ETA, FTA and Common Cause Analysis. Tools available. No task analysis allowed. See also Bow-Tie Analysis using Fault Tree and Event Tree.  |                         |   |   |   | 4 | 5 |   |   |         |             | nuclear,<br>(aircraft)                                       | x      | x      |        |            |  | <ul style="list-style-type: none"> <li>• [Bishop, 1990]</li> <li>• [EN 50128, 1996]</li> <li>• [FAA00]</li> <li>• [Leveson, 1995]</li> <li>• [MUFTIS3.2-I, 1996]</li> <li>• [Rakowsky]</li> <li>• [Ridley &amp; Andrews, 2001]</li> <li>• [ΣΣ93, ΣΣ97]</li> <li>• [Andrews &amp; Ridley, 2002]</li> </ul> |
| 128. | CCFA<br>(Common Cause Failure Analysis)   | Gen,<br>Stat     | HZA     | 1975 | Common Cause Failure Analysis is a generic term for an approach which aims at analysing common cause failures (CCF). Here, a CCF refers to a subset of dependent failures in which two or more component fault states exist at the same time, or within a short interval, as a result of a shared cause. The shared cause is not another component state because such cascading of component states, due to functional couplings, are already usually modelled explicitly in system models. In [FAA00], the procedural steps for a CCFA are: (1) Establish "Critical Tree Groups". This is often accomplished utilizing FMECAs, FTA, and Sneak Circuit Analyses (SCA) to limit the scope of analysis to the critical components or functions or "hidden" interrelationships. (2) Identify common components within the groups of "(1)" above. (3). Identify credible failure modes. (4) Identify common cause credible failure modes. This requires understanding of the system/hardware involved, the use of "lessons learned", and historical data. (5) Summarize analysis results including identification of corrective action. | CCFA is one of the techniques that can be used in a Probabilistic Risk Assessment (PRA). Techniques typically used for CCFA are fault tree analysis, augmented with e.g. the Beta Factor method or the Multiple Greek Letters method, the Alpha Factor method or the Binomial Failure Rate method. In [FAA00], CCFA is referred to as an extension of FTA to identify "coupling factors" that can cause component failures to be potentially interdependent. |                         |   | 3 | 4 | 5 | 6 |   |   |         |             | aircraft,<br>nuclear, space,<br>healthcare, rail,<br>oil&gas | x      | x      |        |            |  | <ul style="list-style-type: none"> <li>• [FAA00]</li> <li>• [Rasmuson &amp; Mosley, 2007]</li> <li>• [Wierman et al., 1999]</li> <li>• [Kelly &amp; Rasmuson, 2008]</li> </ul>  |
| 129. | CCMT<br>(Cell-to-Cell Mapping Technique)  | Math<br>,<br>Dyn | Mod     | 1987 | CCMT is a numerical technique for the global analysis of non-linear dynamic systems. It models system evolution in terms of probability of transitions within a user-specified time interval (e.g., data-sampling interval) between sets of user-defined parameter/state variable magnitude intervals (cells). The cell-to-cell transition probabilities are obtained from the given linear or nonlinear plant model. CCMT uses Matrix solvers as solution method.  | It is particularly useful if the system has a strange attractor. A variation of CCMT is CCCMT (Continuous Cell-to-Cell Mapping Technique) where the Solution method is ODE (ordinary differential equation) solvers rather than Matrix solvers.  |                         |   |   |   | 4 |   |   |   |         |             | nuclear  | x      |        |        |            |  | <ul style="list-style-type: none"> <li>• [Hsu, 1987]</li> </ul>   |

| 130. | CCS<br>(Calculus of Communicating Systems) | Math   | SwD       | 1980          | CCS is an algebra for specifying and reasoning about concurrent systems. As an algebra, CCS provides a set of terms, operators and axioms that can be used to write and manipulate algebraic expressions. The expressions define the elements of a concurrent system and the manipulations of these expressions reveal how the system behaves. CCS is useful for evaluating the qualitative correctness of properties of a system such as deadlock or livelock.  | Introduced by Robin Milner. Formal Method. Descriptive tool in cases where a system must consist of more than one process. Software requirements specification phase and design & development phase.   |                         |   | 2 |   |   |   |   |   |         |                          | software                        |        | x      |        |            |  |  | <ul style="list-style-type: none"> <li>• [Bishop, 1990]</li> <li>• [CCS]</li> <li>• [EN 50128, 1996]</li> <li>• [Rakowsky]</li> </ul> |
| 131. | CDA<br>(Code Data Analysis)                | Step   | SwD       | 1996 or older | Code data analysis concentrates on data structure and usage in the software code. The analysis aims at ensuring that the data items are defined and used properly, and that safety critical data is not being inadvertently altered or overwritten. This is accomplished by comparing the usage and value of all data items in the code with the descriptions provided in the design materials. In addition, there are checks to see if interrupt processing is interfering with safety critical data, and checks of the “typing” of safety critical declared variables.   |  |                         |   | 3 |   |   |   |   |   |         |                          | healthcare, (avionics), (space) |        | x      |        |            |  |  | <ul style="list-style-type: none"> <li>• [NASA-GB-1740.13-96]</li> <li>• [Rakowsky]</li> <li>• [FAA00]</li> </ul>                     |
| 132. | CDM<br>(Critical Decision Method)          | Dat    | Task, Ret | 1989          | The CDM is a semi-structured interview technique developed to obtain information about decisions made by practitioners when performing their tasks. A subject-matter expert is asked to recount a particularly challenging or critical incident in which his/her skills were needed. The operator is asked to provide a general description of the incident followed by a more detailed account of the sequence of events. The interviewer and the operator then establish a timeline and identify the critical points in the incident. The interviewer then uses a number of probes to elicit more detailed information about the problem solving processes at each of the critical points in the incident. The interviewer probes to identify decision points, shifts in situation assessment, critical cues leading to a specific assessment, cognitive strategies, and potential errors. | CDM is a variant of CIT, extended to include probes that elicit aspects of expertise such as the basis for making perceptual discriminations, conceptual discriminations, typicality judgments, and critical cues. Output can be represented in various ways, e.g. through narrative accounts, or in the form of a cognitive requirements table that lists the specific cognitive demands of the task, as well as contextual information needed to develop relevant training or system design recommendations. |                         |   |   |   |   |   |   | 8 |         | navy, healthcare         |                                 |        | x      | x      |            |  | <ul style="list-style-type: none"> <li>• [Klein et al, 1989]</li> <li>• [FAA HFW]</li> </ul>   |   |
| 133. | CDR<br>(Critical Design Review)            | Step   | HwD       | 1989 or older | The CDR demonstrates that the maturity of the design is appropriate to support proceeding with full-scale fabrication, assembly, integration, and test. A CDR is conducted a) to verify that the detailed design of one or more configuration items satisfy specified requirements, b) to establish the compatibility among the configuration items and other items of equipment, facilities, software, and personnel, c) to assess risk areas for each configuration item, and, as applicable, d) to assess the results of productivity analyses, review preliminary hardware product specifications, evaluate preliminary test planning, and evaluate the adequacy of preliminary operation and support documents. Checklists may be used to guide the review process.   | A CDR is held when a major product deliverable has reached a point in design and prototyping work where "viability" of the design can be judged, and by extension, the project can be considered to have reached a state of significantly reduced risk. CDRs are intended to show that a design is complete to a certain level of elaboration. Unlike formal inspections, these reviews are focused more on explaining a design than identifying defects.  |                         |   |   |   |   | 5 |   | 8 |         | space, aircraft, defence | x                               |        |        |        |            |  | <ul style="list-style-type: none"> <li>• [FAA00]</li> <li>• [CDR Template]</li> <li>• [CDR Report]</li> <li>• [CDR Assessments]</li> </ul> |   |

| 134. | CED<br>(Cause and Effect Diagram)<br>or<br>Ishikawa diagram<br>or<br>Fishbone diagram | Stat   | Mod     | 1943          | The Cause And Effect Diagram is a Logic Diagram with a significant variation. It provides more structure than the Logic Diagram through the branches that give it one of its alternate names, the fishbone diagram. The user can tailor the basic "bones" based upon special characteristics of the operation being analyzed. Either a positive or negative outcome block is designated at the right side of the diagram. Using the structure of the diagram, the user completes the diagram by adding causal factors. Causes are usually grouped into major categories to identify sources of variation. The categories are often categorized as "The 6 Ms" (used in manufacturing, and including Machine, Method, Material, Man power, etc), "The 8 Ps (used in service industry and including Product, Price, Place, etc) and "The 5 Ss (used in service industry and including Surroundings, Suppliers, Skills, etc). Using branches off the basic entries, additional hazards can be added.   | Also called the Ishikawa diagram (after its creator, Kaoru Ishikawa of Japan, who pioneered quality management processes in the Kawasaki shipyards, and in the process became one of the founding fathers of modern management), or the Fishbone Diagram (due to its shape) or herringbone diagram. See also 5M model.   |                         |   |   |   | 4 |   |   |   |         |             |        |        | management, manufacturing | x            |            |  |   |  |  |   |                              | • [FAA00] |
| 135. | CEDAR<br>(Comprehensive Electronic Data Analysis and Reporting)                       | Dat    | Dat     | 2010 or older | CEDAR provides air traffic management with an electronic support in assessing air traffic employee performance, managing resources, and capturing safety-related information and metrics. The tool provides a standard interface for the collection, retrieval, and reporting of data from multiple sources. It also automates the creation, management, and storage of facility activities and events; briefing items; Quality Assurance Reviews; technical training discussions; and FAA forms.  |  |                         |   |   |   |   |   |   |   |         |             |        | 8      | <u>ATM</u>                |              |            |  | x |  |  | x | • [ATO SMS Manual v3.0]      |           |

| 136. | CELLO method  | Tab    | Mit     | 1998 or older | CELLO is similar to heuristic or expert evaluation except it is collaborative in that multiple experts, guided by a defined list of design criteria, work together to evaluate the system in question. The criteria may be principles, heuristics or recommendations which define good practice in design and are likely to lead to high quality in use. The criteria represent compiled knowledge derived from psychology and ergonomics theory, experimental results, practical experience and organisational or personal belief. At the conclusion of the inspection an evaluation report is created that details how specific functions or features of the system contravene the inspection criteria and may provide recommendations as to how the design should be changed in order to meet a criterion or criteria. The results of the inspection are reported in a standard form related to the criteria used and the objectives of the inspection. The usual severity grading used is: 1. Show stopper. 2. Inconvenient. 3. Annoyance. | Developed by Nigel Claridge et al at Nomos AB, Sweden. Is largely derived from the expert-based heuristic method promoted by Jacob Neilsen. CELLO can be used throughout the lifecycle but it is most useful when applied early in the development cycle as a check that the user and usability requirements for the system in question are being observed. See also Heuristic Evaluation. |                         |   |   |   | 2 |   |   |   |         |             |        |        | 6                         | (ergonomics) | x          |  | x |  |  |   | • [FAA HFW]<br>• [CELLO web] |           |

Certification ensures that some level of confidence can be assumed regarding the correctness of software.  | Software design & development phase. Note that certified tools and certified translators are usually certified against their respective language or process standards, rather than with respect to safety. |                         |   |   |   |   |   |   | 7 |         |             | electronics   |        | x      |        |            |   | <ul style="list-style-type: none"> <li>[Bishop, 1990]</li> <li>[EN 50128, 1996]</li> <li>[Rakowsky]</li> </ul> |
| 140. | CES (Cognitive Environment Simulation)                       | RTS    | HRA      | 1987          | Human performance assessment. Dynamic. Was developed for simulating how people form intentions to act in nuclear power plant personnel emergencies. CES can be used to provide an objective means of distinguishing which event scenarios are likely to be straightforward to diagnose and which scenarios are likely to be cognitively challenging, requiring longer to diagnose and which can lead to human error. Can also be used to predict human errors by estimating the mismatch between cognitive resources and demands of the particular problem-solving task. | See also CREATE.   |                         |   |   | 4 | 5 |   |   |   |         | nuclear     |   |        | x      |        |            | <ul style="list-style-type: none"> <li>[MUFTIS3.2-I, 1996]</li> <li>[Kirwan, Part 1, 1998]</li> </ul>   |  |
| 141. | CESA (Commission Errors Search and Assessment)               | Step   | HZA, HRA | 2001          | CESA aims to identify and analyse error of commission (EOC) events, and to prioritize them regarding their potential risk-relevance. Module CESA-Q addresses the quantification, by using Bayesian Belief Networks to analyse EOCs in terms of plant- and scenario-specific situational and adjustment factors that may motivate inappropriate decisions.  | Developed at Paul Scherrer Institute, Switzerland, in 2001. The CESA-Q module was added in 2009-2013.  |                         |   | 3 | 4 | 5 |   |   |   |         | nuclear     |   |        | x      |        |            | <ul style="list-style-type: none"> <li>[Reer, 2008]</li> <li>[Podofillini et al, 2010]</li> <li>[HRA Washington, 2001]</li> <li>[Dang et al, 2002]</li> <li>[Podofillini et al., 2014]</li> </ul> |  |
| 142. | CFA (Cognitive Function Analysis)                            | Step   | Task     | 1998          | Cognitive Function Analysis (CFA) is a methodology that enables a design team to understand better the right balance between cognitive functions that need to be allocated to human(s) and cognitive functions that can be transferred to machine(s). Cognitive functions are described by eliciting the following inputs: task requirements; users, background (skills and knowledge to cope with the complexity of the artifact to be controlled); users' own goals (intentional actions); and external events (reactive actions).                                     | Developed by Guy A. Boy, Florida Institute of Technology.  |                         | 2 |   |   |   |   |   |   |         | aviation    |   |        | x      |        |            | <ul style="list-style-type: none"> <li>[FAA HFW]</li> <li>[Boy, 2014]</li> </ul>  |  |

Considers switching as a general case of impulses; the general term is jump. Each jump goes to a new dynamical system.  |  |                         |   |   | 4 |   |   |   |   |         |             |                                     | (electronics), (manufacturing), (avionics) | x      | x      | x          | x | x |   | <ul style="list-style-type: none"> <li>• [Branicky &amp; Borcar&amp; Mitter, 1998]</li> </ul>  |
|      | Chain of Multiple Events                              |        |         |        |  | See Domino Theory  |                         |   |   |   |   |   |   |   |         |             |                                     |  |        |        |            |   |   |   |  |
| 145. | Change Analysis                                       | Step   | HZA     | 1965 ? | Change Analysis examines the effects of modifications from a starting point or baseline. It is a technique designed to identify hazards that arise from planned or unplanned change. Four steps: 1) review previous operation / current practice; 2) Review operational analysis of planned operation; 3) For each step / phase of the operation, identify differences (“changes”) between the two; 4) Determine impact on risk of the operation. The change analysis systematically hypothesises worst-case effects from each modification from the baseline. | Cause-Consequence analysis is also used during accident/incident investigation.  |                         | 2 | 3 |   | 5 |   |   |   |         |             |                                     | healthcare, management, aviation           | x      |        |            |   | x | x | <ul style="list-style-type: none"> <li>• [FAA AC431]</li> <li>• [FAA00]</li> <li>• [ORM]</li> <li>• [ΣΣ93, ΣΣ97]</li> <li>• [FAA HFW]</li> </ul> |

| 146. | CHASE<br>(Complete Health And Safety Evaluation)      | Tab    | Org     | 1987   | CHASE is a general management health and safety audit method for general industry. There are two versions: CHASE-I is for small and medium sized organisations, CHASE-II is for large organisations (100+ employees). CHASE is comprised of sections (4 in CHASE-I; 12 in CHASE-II) which include a number of short questions. Answering Yes gives 2-6 points depending on the activity assessed; answering No gives zero points. The scores on the sub-sets of safety performance areas are weighted and then translated into an overall index rating.        | Qualitative. Developed by HASTAM Ltd., UK. Designed for both monitoring by line managers and auditing by safety professionals. The questions consider the management of e.g. legal requirements and resources, machinery and plant, chemicals and substances, vehicles, energy, health, tasks, people, change, emergencies, etc. |                         |   |   |   |   |   |   | 7 | 8       |             | (manufacturing), (police), (social) |  |        |        |            | x |   |   | <ul style="list-style-type: none"> <li>• [Kennedy &amp; Kirwan, 1998]</li> <li>• [Kuusisto, 2001]</li> </ul>                                     |

| 147. | CHIRP<br>(Confidential Human Factors Incident Reporting Programme) | Dat    | Dat     | 1982 | The aim of CHIRP is to contribute to the enhancement of flight safety in the UK commercial and general aviation industries, by providing a totally independent confidential (not anonymous) reporting system for all individuals employed in or associated with the industries. Reporters' identities are kept confidential. Important information gained through reports, after being disidentified, is made available as widely as possible. CHIRP provides a means by which individuals are able to raise issues of concern without being identified to their peer group, management, or the Regulatory Authority. Anonymous reports are not normally acted upon, as they cannot be validated.  | CHIRP has been in operation since 1982 and is currently available to flight crew members, air traffic control officers, licensed aircraft maintenance engineers, cabin crew and the GA (General Aviation) community. Example issues are those related to work hours, rest periods, and fatigue. Since 2003, there is also a CHIRP for maritime (shipping industry, fishing industry, leisure users), named Confidential Hazardous Incident Reporting Programme.   |                         |   |   |   |   |   |   |   |         | 8           | aviation, ATM, aircraft, maritime |        |        | x      | x          | x |   |  |  | <ul style="list-style-type: none"> <li>• [CHIRP web]</li> <li>• For other systems like this, see [EUCARE web]</li> <li>• [GAIN ATM, 2003]</li> </ul> |
| 148. | CI<br>(Contextual Inquiry)   | Dat    | Dat     | 1988 | Contextual Inquiry is both a form of field study, semi-structured interview method and a data analysis technique. Experimenters observe users in their normal working environment and record both how the users work and the experimenters' interaction with the users. This recording can be hand-written notes or, if possible, through the use of video or audiotape recordings. The aim is to gather details of work, discovering parameters, criteria, features, or process flows for design or redesign.   | The notes may be organised in an Affinity Diagram. See also Plant walkdowns/ surveys. See also Field Study. See also Interview.   |                         |   |   | 2 |   |   |   |   |         |             | electronics, healthcare           |        |        |        | x          |   |   |  |  | <ul style="list-style-type: none"> <li>• [FAA HFW]</li> <li>• [Fouskas et al., 2002]</li> </ul>  |
| 149. | CIA<br>(Cross Impact Analysis)                                     | Int    | OpR     | 1966 | CIA is a family of techniques that aims to connect relationships between events and variables. These relationships are then categorized as positive or negative to each other, and are used to determine which events or scenarios are most probable or likely to occur within a given time frame. In its original form ('The Futures Forecasting Style'), CIA follows five steps: 1) Identify the number and type of events to be considered in the analysis and create an event set. Typically, 10 to 40 events are used. 2) Identify the initial probability of each individual event, independent from other events. 3) Generate, for each possible interaction between events, conditional probabilities that events have on each other. 4) Test the initial conditional probabilities to ensure that there are no mathematical errors. This is usually done by running simulations in a computer several times. 5) Run the analysis to determine future scenarios, or determine how significant other events are to specific events. | Developed by Theodore Gordon and Olaf Helmer in 1966. Later expanded by other researchers. The outcome of applying a cross-impact model is a production of scenarios. Each run of the model produces a synthetic future history, or scenario, which includes the occurrence of some events and the non-occurrence of others. The primary focus of this process is to generate forecasting studies of the iterations of the probability of one event affecting another so interactions are definitely considered and possible futures. |                         |   |   |   |   |   |   | 5 |         |             | finance, nuclear, road, aviation  | x      | x      | x      | x          | x | x |  |  | <ul style="list-style-type: none"> <li>• [Gordon, 1994]</li> </ul>   |

| 150. | CIA<br>(Code Interface Analysis)                   | Step   | SwD       | 1996 or older | Code interface analysis verifies the compatibility of internal and external interfaces of a software component and is intended to verify that the interfaces have been implemented properly. A software component is composed of a number of code segments working together to perform required tasks. These code segments must communicate with each other, with hardware, other software components, and human operators to accomplish their tasks. The analysis includes a check that parameters are properly passed across interfaces, since each of these interfaces is a source of potential problems. |   |                         |   | 3 |   |   |   |   |   |  |                                   | software, (avionics), (space) |        | x      |        |            |   |   | <ul style="list-style-type: none"> <li>• [FAA00]</li> <li>• [NASA-GB-1740.13-96]</li> <li>• [Rakowsky]</li> </ul> |
| 151. | CIRS<br>(Critical Incident Reporting System)       | Dat    | Dat, Ret  | 1997          | Collects anonymous critical anaesthesia incident reports to gain insight into the nature of critical events. CIRS defines a critical incident as any deviation from an expected course with potential for an adverse outcome.  |   |                         |   |   |   |   |   |   |   | 8  | (healthcare)                      |                               |        |        | x      | x          | x   |   | <ul style="list-style-type: none"> <li>• [Salmon et al., 2005]</li> </ul>   |
| 152. | CIT<br>(Critical Incident Technique)               | Step   | HZA, Task | 1954          | This is a method of identifying errors and unsafe conditions that contribute to both potential and actual accidents or incidents within a given population by means of a stratified random sample of participant-observers selected from within the population. Operational personnel can collect information on potential or past errors or unsafe conditions. Hazard controls are then developed to minimise the potential error or unsafe condition.  | This technique can be applied in any operational environment. Generally, the technique is most useful in the early stages of a larger task or activity.   |                         |   |   |   |   |   | 7 | 8 | aviation, ATM, nuclear, healthcare, manufacturing, defence, social, management | x                                 |                               | x      |        |        | x          | <ul style="list-style-type: none"> <li>• [Flanagan, 1954]</li> <li>• [FAA00]</li> <li>• [Infopolis2]</li> <li>• [Kirwan, 1994]</li> <li>• [Kirwan &amp; Ainsworth, 1992]</li> <li>• [ΣΣ93, ΣΣ97]</li> <li>• [MIL-HDBK 46855A]</li> <li>• [FAA HFW]</li> </ul> |   |   |
| 153. | CLA<br>(Check List Analysis or Checklist Analysis) | Tab    | HZI       | 1974          | Checklist Analysis is a comparison to criteria, or a device to be used as a memory jogger. The analyst uses a list to identify items such as hazards, design or operational deficiencies. Checklists enable a systematic, step by step process. They can provide formal documentation, instruction, and guidance.  | Checklist Analysis can be used in any type of safety analysis, safety review, inspection, survey, or observation. Combines with What-if analysis. See also Ergonomics Checklists. | 154. | CLA<br>(Code Logic Analysis)                       | Step   | SwD       | 1996 or older | Code Logic Analysis aims to detect logic errors in a given software code. This analysis is conducted by performing logic reconstruction (which entails the preparation of flow charts from the code and comparing them to the design material descriptions and flow charts), equation reconstruction (which is accomplished by comparing the equations in the code to the ones provided with the design materials) and memory coding (which identifies critical instruction sequences even when they may be disguised as data).  |   |                         |   | 3 |   |   |   |   |   |  | software, (avionics), (space)     |                               | x      |        |        |            |   | <ul style="list-style-type: none"> <li>• [FAA00]</li> <li>• [NASA-GB-1740.13-96]</li> <li>• [Rakowsky]</li> </ul> |   |

| 155. | ClusterGroup                           | Int    | Dec?    | 2002 | ClusterGroup uses cluster analysis techniques to facilitate the prioritisation of the importance of aviation safety risk factors by groups of experts. Aims to gain an understanding of the rationale behind decisions made in situations involving risk. It uses various clustering algorithms to aggregate similar opinions of groups of experts into "majority" and "minority" clusters. The underlying methodology eliminates the necessity of performing numerous pairwise comparisons.   | Up to 80% reduction in the number of computations is reported possible, yet results are said to compare favorably with more traditional methods, such as the AHP.  |                         |   |   |   |   | 5 |   |   |         |             |        | (aviation)  |        |        | x          |   |  |  | <ul style="list-style-type: none"> <li>[Luxhøj, 2002]</li> <li>[Maurino &amp; Luxhøj, 2002]</li> <li>[Ammarapala, 2002]</li> </ul>  |
| 156. | CM<br>(Configuration Management)       | Gen    | Des     | 1950 | Configuration management is a field of management that focuses on establishing and maintaining consistency of a system's or product's performance and its functional and physical attributes with its requirements, design, and operational information throughout its life. Aim is to ensure the consistency of groups of development deliverables as those deliverables change.  | Tools available. Configuration management was first developed by the United States Air Force for the Department of Defense in the 1950s as a technical management discipline of hardware. It is now being used in many domains. Its application to software is referred to as SCM; see also SCM. |                         |   |   |   |   |   |   | 6 |         |             |        | defence,<br>aircraft,<br>manufacturing                      | x      |        |            |   |  |  | <ul style="list-style-type: none"> <li>[Bishop, 1990]</li> </ul>  |
| 157. | CMA<br>(Confusion Matrix Analysis)     | Tab    | HRA     | 1981 | Determines human reliability. Is aimed specifically at two of the diagnostic error-forms, namely misdiagnoses and premature diagnoses. A confusion matrix is an array showing relationships between true and predicted classes. Typically the variables are an observation and a prediction. Each row in the confusion matrix represents an observed class, each column represents a predicted class, and each cell counts the number of samples in the intersection of those two classes. Probabilities can be derived experimentally or using expert judgments.  | Is sometimes followed after an FSMA.   |                         |   |   |   |   | 5 |   |   |         |             |        | environment,<br>healthcare,<br>finance, social,<br>chemical |        |        |            | x |  |  | <ul style="list-style-type: none"> <li>[Kirwan, 1994]</li> <li>[Kirwan, Part 1, 1998]</li> <li>[MUFTIS3.2-I, 1996]</li> <li>[GAIN ATM, 2003]</li> <li>[FAA HFW]</li> <li>[CM]</li> <li>[Potash, 1981]</li> <li>[Volpe, 1998]</li> </ul> |
| 158. | CMA<br>(Common Mode Analysis)          | Step   | HwD     | 1987 | CMA provides evidence that the failures assumed to be independent are truly independent in the actual implementation. It covers the effect of design, manufacturing and maintenance errors and the effects of common component errors. A common mode failure has the potential to fail more than one safety function and to possibly cause an initiating event or other abnormal event simultaneously. The analysis is complex due to the large number of common mode failures that may be related to the different common mode types such as design, operation, manufacturing, installation and others. | CMA is the third step in a Common Cause Analysis (CCA). Particular Risks Assessment is the second, and provides input to the CMA.  |                         |   |   | 3 |   |   |   |   |         |             |        | aircraft  | x      | x      |            |   |  |  | <ul style="list-style-type: none"> <li>[ARP 4761]</li> <li>[Mauri, 2000]</li> </ul>   |
| 159. | CMFA<br>(Common Mode Failure Analysis) | Step   | HwD     | 1972 | Aim is to identify potential failures in redundant systems or redundant sub-systems that would undermine the benefits of redundancy because of the appearance of the same failures in the redundant parts at the same time.  | The technique is not well developed but is necessary to apply, because without consideration of common mode failures, the reliability of redundant systems would be over-estimated. Related methods: ETA, CCA, FMEA.   |                         |   |   | 3 |   |   |   |   |         |             |        | road, nuclear   | x      | x      |            |   |  |  | <ul style="list-style-type: none"> <li>[Bishop, 1990]</li> </ul>  |

| 161. | COCOM<br>(Contextual Control Model)                               | Stat   | HFA     | 1993         | COCOM models human performance as a set of control modes - strategic (based on long-term planning), tactical (based on procedures), opportunistic (based on present context), and scrambled (random) - and proposes a model of how transitions between these control modes occur. This model of control mode transition consists of a number of factors, including the human operator's estimate of the outcome of the action (success or failure), the time remaining to accomplish the action (adequate or inadequate), and the number of simultaneous goals of the human operator at that time.   | Developed by Erik Hollnagel. Also used within TOPAZ.  |                         |   |   |   | 4 |   |   |   |         |             |        |        |        |        |            |  |  | <ul style="list-style-type: none"> <li>[Hollnagel, 1993]</li> <li>[Cacciabue, 1998]</li> <li>[Kirwan, Part 1, 1998]</li> <li>[COCOM web]</li> <li>[Hollnagel &amp; Nabo &amp; Lau, 2003]</li> <li>[Daams &amp; Blom &amp; Nijhuis, 2000]</li> </ul> |
| 162. | CODA<br>(Conclusions from Occurrences by Descriptions of Actions) | Step   | Ret     | 1997         | Method for analysing human-related occurrences (i.e., incorrect human responses) from event cases retrospectively. The CODA method uses an open list of guidelines based on insights from previous retrospective analyses. It is recommended in this method to compile a short story that includes all unusual occurrences and their essential context without excessive technical details. Then the analysis should envisage major occurrences first. For their description, the method presents a list of criteria which are easy to obtain and which have been proved to be useful for causal analysis. For their causal analysis, various guidelines are provided. They are mainly of holistic, comparative and generalising nature. It is demonstrated by various event cases that CODA is able to identify cognitive tendencies (CTs) as typical attitudes or habits in human decision-making. | Quantification may be done with expert judgement or THERP.  |                         |   |   | 3 | 5 |   |   |   |         |             |        |        |        |        |            |  |  | <ul style="list-style-type: none"> <li>[Reer, 1997]</li> <li>[Straeter et al, 1999]</li> </ul>  |
| 163. | Code Analysis   | Step   | SwD     | 1995 about ? | Code analysis verifies that the coded program correctly implements the verified design and does not violate safety requirements. The techniques used in the performance of code analysis mirror those used in design analysis.   |   |                         |   |   |   |   |   |   |   | 7       |             |        |        |        |        |            |  |  | <ul style="list-style-type: none"> <li>[FAA00]</li> <li>[NASA-GB-1740.13-96]</li> <li>[Rakowsky]</li> </ul>   |

| 168. | COGNET<br>(Cognition as a Network of Tasks) | Stat   | Task    | 1989 | COGNET is a framework for creating and exercising models of human operators engaged in primarily cognitive (as opposed to psychomotor) tasks. Its purpose is to develop user models for intelligent interfaces. It has been used to model surrogate operators (and opponents) in submarine warfare simulations. The most important assumption behind COGNET is that humans perform multiple tasks in parallel. These tasks compete for the human's attention, but ultimately combine to solve an overall information-processing problem. COGNET is based on a theory of weak task concurrence, in which there are at any one time several tasks in various states of completion, though only one of these tasks is executing. That is, COGNET assumes serial processing with rapid attention switching, which gives the overall appearance of true parallelism. | Development of COGNET was led by Dr. W. Zachary, CHI Systems. The basis for the management of multiple, competing tasks in COGNET is a pandemonium metaphor of cognitive processes composed of "shrieking demons", proposed by Selfridge (1959). In this metaphor, a task competing for attention is a demon whose shrieks vary in loudness depending on the problem context. The louder a demon shrieks, the more likely it is to get attention. At any given time, the demon shrieking loudest is the focus of attention and is permitted to execute. |                         | 2 |   |   | 5 |   |   |   |         |             | navy, ATM, electronics |        |        | x      |            |  |  | <ul style="list-style-type: none"> <li>• [GAIN ATM, 2003]</li> <li>• [Zachary, 1996]</li> <li>• [FAA HFW]</li> <li>• [Morrison, 2003]</li> </ul> |

| 169. | COMET<br>(COMmission Event Trees)           | Stat   | HRA     | 1991 | Modified event trees that deal with errors of commission and cascading errors whose source is either erroneous intention or a latent error. COMETs are developed e.g., using SNEAK, and are basically event trees, their results feeding into fault trees. The main significance of this approach appears to be as a means of integrating errors of commission into PSA and quantifying them. It does not help too much in terms of actually identifying errors of commission.  | Relation with SNEAK and ETA.  |                         |   |   | 4 |   |   |   |   |         | nuclear     |                        |        | x      |        |            |  | <ul style="list-style-type: none"> <li>• [Kirwan, Part 1, 1998]</li> </ul> |  |
| 170. | Comparison Risk Analysis                    | Step   | OpR     | 1995 | Is used during the design of new plants (and modifications) in order to predict the occupational accident-frequency rate for the plant during operation. Results are expressed as relative changes in the accident-frequency rate in relation to the experienced rate of a reference plant that has been in operation for some years. Method follows four steps: 1) Establishment of a database for the reference installation; 2) Grouping of the accidents with respect to area and activity; 3) Establishment of a simulated database for the analysis object; 4) Estimation of the injury-frequency rate for the analysis object.   | Method was originally developed to meet the Norwegian risk-analysis regulations for the offshore industry. See also Severity Distribution Analysis.   |                         |   |   |   | 5 |   |   |   |         | (oil&gas)   | x                      |        |        |        |            |  | <ul style="list-style-type: none"> <li>• [Kjellen, 2000]</li> </ul>        |  |
| 171. | Complexity Models                           | Gen    | SwD     | 1971 | Aim is to predict the reliability of programs from properties of the software itself (e.g. number of program steps) rather than from its development or test history.   | Can be used at the design, coding and testing phase to improve quality of software by the early identification of over-complex modules and by indicating the level of testing required for different modules. Tools available.  |                         |   | 3 |   |   |   |   |   |         | software    |                        | x      |        |        |            |  | <ul style="list-style-type: none"> <li>• [Bishop, 1990]</li> </ul>         |  |

| 172. | Computer Modelling and Simulation               | RTS, FTS | Mod     | 1978 or older | Involves the use of computer programs to represent e.g. operators and/or system activities or features. Human performance data that have been previously collected, or estimates of task components, error probabilities, etc., are entered into the computer program. The program either can then simulate graphically the environment and workspace or can dynamically run the task in real or fast time as a way of estimating complete cycle times and error likelihoods, etc.  | Four well-known variants are often referred to as Real-Time Simulation (simulator clock runs with speed according to real clocks), Fast Time Simulation (simulator clock does not run with speed according to real clocks, and can even make jumps), Discrete Event Simulation, and Monte Carlo simulation. |                         |   |   |   | 4 | 5 |   |   |         |   | chemical, social, finance, ATM, aviation, nuclear, rail, road, ergonomics, leisure, security | x      |        | x      | x          | x |                             | • [Kirwan & Ainsworth, 1992]                               |
| 173. | Conceptual Graph Analysis                       | Stat     | HFA     | 1976          | Conceptual graph analysis is a method of visually depicting internal knowledge structures during a cognitive task analysis. These graphs consist of nodes connected via arcs. The nodes contain either single concepts or single statements. Constructing a conceptual graph is similar to concept mapping, but it includes a formal and detailed collection of nodes, relations, and questions. The nodes can include more than just concepts. Nodes can be goals, actions, or events. There are specific relations for each type of node, and a set of formal, probing questions is developed for each node type.   | Conceptual Graphs were first used by John Sowa in 1976.   |                         |   |   |   | 4 |   |   |   |         |   | road, aviation, environment, social  |        |        | x      |            |   |                             | • [Jonassen et al, 1999]<br>• [FAA HFW]<br>• [Dieng, 1997] |
| 174. | ConDOR (Constructed Dynamic Observation Report) | Dat      | Hzi     | 2006 or older | ConDOR is used for focused, special inspections, and for identification of more specific information about a hazard or risk. It allows data collection activities to be requested or assigned with instructions to inspect and report on specific areas of immediate concern outside of the normal assessment schedule. ConDOR may be appropriate in the following instances: A). To evaluate program, policy, or regulatory changes. B). To address focused or unique situations in response to local, regional, or national requirements. C). To collect targeted data for specific areas of immediate concern. D). As an action item in the risk management process action plan. E). To document minor changes to the air carrier's system (e.g., changes to the individual identified by the certificate holder as having responsibility and/or authority over the process). F). If the air carrier presents a revision to a manual that only changes a reference, a DA may not be necessary. |   |                         |   |   |   | 3 |   |   |   | 7       |   | aircraft   | x      |        |        |            | x |                             | • [FAA FSIMS, 2009]  |

| 175. | Contingency Analysis                            | Step     | Mit     | 1972 ?        | Contingency Analysis is a method of minimising risk in the event of an emergency. Potential accidents are identified and the adequacies of emergency measures are evaluated. Contingency Analysis lists the potential accident scenario and the steps taken to minimise the situation.  | Contingency Analysis can be conducted for any system, procedure, task or operation where there is the potential for harm. It is an excellent formal training and reference tool.  |                         |   |   |   | 3 |   |   | 6 |         | nuclear, electronics, oil&gas, chemical, ATM, aviation, airport, navy, healthcare | x  |        | x      | x      |            |   | • [FAA00]<br>• [ΣΣ93, ΣΣ97] |  |

| 176. | Control Flow Checks or Control Flow Analysis                                | Stat   | Hzi      | 1981      | Control flow analysis is a static code analysis technique for determining at compile time which functions may be applied at run time, i.e. it determines the control flow of a program. For many languages, the control flow of a program is explicit in a program's source code. As a result, control-flow analysis implicitly usually refers to a static analysis technique for determining the receiver(s) of function or method calls in computer programs written in a higher-order programming language. For both functional programming languages and object-oriented programming languages, the term CFA refers to an algorithm that computes control flow. Aim is to detect computer mal-operation by detecting deviations from the intended control flow. | Not necessary if the basic hardware is fully proven or self-checking. Otherwise, it is valuable technique for systems that can fail to a safe state where there is no hardware redundancy or no software diversity in the program or support tools. Tools available. | 179. | COSIMO<br>(Cognitive Simulation Model) | RTS<br>? | HFA          | 1992 | A parallel to CES in that it is a simulation of the human operator and his/her thought processes, using a computerised blackboard architecture. The simulated operator comprises a set of properties and attributes associated with particular incident scenarios, and 'packets' of process knowledge and heuristics rules of thumb. When diagnosing, each scenario and its associated attributes are contrasted to 'similarity-match' to the symptom set being displayed to the 'operator', and the simulated operator will either determine unequivocally which scenario matches the symptoms, or, if there is ambiguity, will 'frequency- gamble'. Once hypotheses are formulated, they are evaluated according to a confidence threshold, and may be accepted or rejected.   |   |                         | 2 |   |   |   | 5 |   |   |         |  | nuclear |        |        | x      |            |  | <ul style="list-style-type: none"> <li>• [Kirwan, 1995]</li> <li>• [Kirwan, Part 1, 1998]</li> <li>• [MUFTIS3.2-I, 1996]</li> </ul> |
| 180. | CPA<br>(Critical Path Analysis)        | Stat     | HZI,<br>Task | 1957 | Critical Path Analysis is an algorithm for scheduling a set of project activities. The technique is to construct a model of the project that includes a list of all activities required to complete the project (typically categorized within a work breakdown structure), the time (duration) that each activity will take to completion, and the dependencies between the activities. Next, CPA calculates the longest path of planned activities to the end of the project, and the earliest and latest that each activity can start and finish without making the project longer. This process determines which activities are "critical" (i.e., on the longest path) and which have "total float" (i.e., can be delayed without making the project longer). Any delay of an activity on the critical path directly impacts the planned project completion date. | Project modeling technique developed in the late 1950s by Morgan R. Walker of DuPont and James E. Kelley, Jr. of Remington Rand. This technique is applied in support of large system safety programs, when extensive system safety-related tasks are required. Combines with PERT. Tools available. | 181. | CPIT<br>(Cabin Procedural Investigation Tool) | Int    | Ret     | 2002 | The CPIT process focuses on a cognitive approach to understand how and why the event occurred, not who was responsible. CPIT depends on an investigative philosophy, which acknowledges that professional cabin crews very rarely fail to comply with a procedure intentionally, especially if it is likely to result in an increased safety risk. It also requires the airline to explicitly adopt a non-jeopardy approach to incident investigation. CPIT contains more than 100 analysis elements that enable the user to conduct an in-depth investigation, summarise findings and integrate them across various events. The CPIT data organisation enables operators to track their progress in addressing the issues revealed by the analyses. CPIT is made up of two components: the interview process and contributing analysis. It provides an in-depth structured analytic process that consists of a sequence of steps that identify key contributing factors to cabin crew errors and the development of effective recommendations aimed at the elimination of similar errors in the future. | The CPIT approach, developed by Boeing, has benefited from lessons learned by its sister program, Procedural Event Analysis Tool (PEAT), which Boeing has provided to airlines since 1999. CPIT is a stand-alone service, but is normally offered with PEAT training.  |                         |   |   |   |   |   |   |   |         |             | 8      | aviation    |        |        | x          |   |  |  | • [GAIN AFSA, 2003] |

| 182. | CPM-GOMS<br>(Cognitive-Perceptual-Motor GOMS) | Stat   | Task    | 1988 | CPM-GOMS builds on previous GOMS models by assuming that perceptual, cognitive and motor operators can be performed in parallel. Where other GOMS techniques assume that humans do one thing at a time, CPM-GOMS assumes as many operations as possible will happen at any given time subject to constraints of the cognitive, perceptual, and motor processes. Models are developed using PERT charts and execution time is derived from the critical path. CPM-GOMS generally estimates unit-tasks serial executions to be faster than the other version of GOMS. This happens because the model assumes that the users are expert and are executing the operations as fast as the Model Human Processor can perform.  | CPM-GOMS is a variation of the GOMS technique in human computer interaction. CPM stands for two things: Cognitive, Perceptual, and Motor and the project planning technique Critical Path Method (from which it borrows some elements). CPM-GOMS was developed in 1988 by Bonnie John, a former student of Allen Newell. Unlike the other GOMS variations, CPM-GOMS does not assume that the user's interaction is a serial process, and hence can model multitasking behavior that can be exhibited by experienced users. The technique is also based directly on the model human processor - a simplified model of human responses. | 183. | CPQRA<br>(Chemical Process Quantitative Risk Analysis)     | Step     | OpR          | 1989      | Quantitative risk assessment within chemical process industry. Stands for the process of hazard identification, followed by numerical evaluation of incident consequences and frequencies, and their combination into an overall measure of risk when applied to the chemical process industry. Ordinarily applied to episodic events.  | Processes of all types. Is related to Probabilistic Risk Assessment (PRA) used in the nuclear industry.   |                         |   |   | 3 | 4 | 5 |   |   |         |             |        | chemical   | x      |        |            |   |  | <ul style="list-style-type: none"> <li>• [ΣΣ93, ΣΣ97]</li> <li>• [CPQRA]</li> <li>• [CPQRA2]</li> </ul>   |
| 184. | CRC<br>(Control Rating Code Method)                        | Tab      | Mit          | 1980<br>? | Control Rating Code aims to prioritise hazard control options that are found during risk analysis or accident analysis. A number of candidate strategies to control hazards is assessed regarding various control types, i.e. Design change (engineering type controls that potentially eliminate the hazard); Passive control (controls that are in place that do not require human intervention); Active control (controls that are in place that require humans to activate them); Warning device (alarms or monitoring that indicate a hazardous situation); Procedure (documented standard operating procedures that control the hazardous situation). The assessments are then used to determine a ranking of strategies. | Control Rating Code can be applied when there are many hazard control options available.  |                         |   |   |   |   |   | 6 |   |         |             |        | defence, mining                                    | x      |        |            |   |  | <ul style="list-style-type: none"> <li>• [FAA AC431]</li> <li>• [FAA00]</li> <li>• [ΣΣ93, ΣΣ97]</li> <li>• [White Benner, 2005]</li> <li>• [Henderson, 2009]</li> <li>• [Benner, 2008]</li> </ul> |
| 185. | CREAM<br>(Cognitive Reliability and Error Analysis Method) | Step     | HRA<br>, Ret | 1998      | Cognitive modelling approach. Applies cognitive systems engineering to provide a more thoroughly argued and theory supported approach to reliability studies. The approach can be applied retrospectively or prospectively, although further development is required for the latter. The 'meat' of CREAM is the distinction between phenotypes (failure modes) and genotypes (possible causes or explanations).   | Developed by Erik Hollnagel. Related to SHERPA, SRK and COCOM. A version of traffic safety has been implemented (DREAM - Driver Reliability And Error Analysis Method). Later, a version was developed for use in maritime accident analysis (BREAM - B for the ship's Bridge). |                         |   |   | 4 |   |   |   |   |         |             |        | nuclear, rail, manufacturing, healthcare, chemical |        |        | x          |   |  | <ul style="list-style-type: none"> <li>• [Kirwan, Part 1, 1998]</li> <li>• [CREAM web]</li> <li>• [FAA HFW]</li> </ul>  |

| 188. | CREWS approach (Cooperative Requirements Engineering With Scenarios) | Step   | OpR, Mit | 1998          | The ESPRIT CREWS approach focuses more on goal definition and the linking of goals to stakeholders' actual needs by linking goals and scenarios. It uses a bi-directional coupling allowing movement from goals to scenarios and vice-versa. The complete solution is in two parts: when a goal is discovered, a scenario can be authored for it and once a scenario has been authored, it is analysed to yield goals. By exploiting the goal-scenario relationship in the reverse direction, i.e. from scenario to goals, the approach pro-actively guides the requirements elicitation process. In this process, goal discovery and scenario authoring are complementary steps and goals are incrementally discovered by repeating the goal-discovery, scenario-authoring cycle. The steps are: 1. Initial Goal Identification; 2. Goal Analysis; 3. Scenario Authoring; 4. Goal Elicitation through Scenario Analysis. Steps 2 - 4 are repeated until all goals have been elicited   | CREWS has been developed as part of ESPRIT, a European Strategic Program on Research in Information Technology and ran from 1983 to 1998. ESPRIT was succeeded by the Information Society Technologies (IST) programme in 1999. | 189. | CREWSIM (CREW SIMulation)  | RTS    | HFA      | 1993          | Simulation model that models the response of an operating team in a dynamically evolving scenario. The model simulates operator interactions within a three-person crew, as well as the cognitive processes of the crewmembers, and the crew-plant dynamic interaction. Although the model has a knowledge base as other simulations do (e.g. COSIMO and CES), CREWSIM differs by using a set of prioritised lists that reflect the priorities of different concerns. Some other interesting aspects are 1) attentional resources control is simulated, such that diagnosis will be suspended while the operator is communicating or carrying out some other task. 2) the model's usage focuses particularly on transitions between procedures, and hence is looking in particular for premature, delayed, and inappropriate transfer within the emergency procedures system. 3) several error mechanisms are treated by the model: memory lapse; jumping to conclusions; communication failures; incorrect rules; and improper prioritisation. | Has been particularly developed to date to focus on a particular nuclear power plant scenario.  |                         |   |   | 3 | 4 |   |   |   |         |             | (nuclear)       |        |        |        | x          | x |   | <ul style="list-style-type: none"> <li>[Kirwan, Part 1, 1998]</li> </ul>  |
| 190. | CRIOP (CRisis Intervention in Offshore Production)                   | Tab    | HZA      | 1989 and 2004 | CRIOP is a structured method for assessing offshore control rooms. The main focus is to uncover potential weaknesses in accident/incident response. CRIOP assesses the interface between operators and technical systems within the control room. The assessment is comprised of two main parts: (1) a design assessment in the form of a checklist; and (2) a scenario based assessment intended to assess the adequacy of response to critical situations.  | Developed by the Norwegian Oil & Gas industry. It underwent a significant revision in 2004.   |                         |   |   |   |   |   |   | 7 | 8       | oil&gas     | x               |        |        |        | x          |   | <ul style="list-style-type: none"> <li>[CRIOP History]</li> <li>[Kjellen, 2000]</li> <li>[SAFETEC web]</li> </ul> |   |

| 191. | Criticality Analysis or Criticality Matrix                      | Tab    | HwD       | 1967 | The purpose of the Criticality Analysis is to rank each failure mode identified in a Failure Modes and Effect Analysis. Once critical failures are identified they can be equated to hazards and risks. Designs can then be applied to eliminate the critical failure, thereby eliminating the hazard and associated accident risk.   | The technique is applicable to all systems, processes, procedures, and their elements. Combines with FMEA to become FMECA. See also Nuclear Criticality Analysis.   |                         |   |   |   |   | 5 |   |   |         |             |   | defence, space | x      | x      |            |   |   | <ul style="list-style-type: none"> <li>• [FAA00]</li> <li>• [ΣΣ93, ΣΣ97]</li> </ul> |

| 192. | CRM (Crew Resource Management)                                  | Int    | HRA, Trai | 1979 | CRM is a procedure and training system for operations where human error can have devastating effects. It examines the implications of human factors and limitations, and the effect they have on performance. It introduces the concept of the 'Error Chain', the application of which can lead to recognition of incipient error situations, and develops tools for error intervention and avoidance. CRM is concerned not so much with the technical knowledge and skills required to operate equipment but rather with the cognitive and interpersonal skills needed to manage resources within an organised system.   | Cognitive skills are defined as the mental processes used for gaining and maintaining situation awareness, for solving problems and for making decisions. Interpersonal skills are regarded as communications and a range of behavioral activities associated with teamwork. In aviation, CRM is sometimes referred to as Cockpit Resource Management. In the maritime industry, it is referred to as BRM (Bridge Resource Management). For aircraft maintenance, and for maritime, the term MRM is in use. |                         |   |   |   |   |   | 6 |   |         |             | aviation, oil&gas, healthcare, defence, police, leisure, ATM, aircraft, maritime, nuclear, rail |                |        |        | x          | x | <ul style="list-style-type: none"> <li>• [TRM web]</li> <li>• [Salmon et al, 2005]</li> </ul>                           |   |
| 193. | CRM (Collision Risk Model of the ICAO Obstacle Clearance Panel) | Math   | Col       | 1980 | This is a method to calculate the probability of a collision with obstacles by an aircraft on an ILS (Instrument Landing System) approach and possible subsequent missed approach. It is assumed that aircraft are distributed around a nominal path due to factors such as wind conditions, instrument performance and flight technical error. The risk presented by an obstacle depends on the location of the obstacle relative to the nominal approach path of the aircraft and on the extent to which the aircraft are likely to spread the nominal path at the range of the obstacle. Visual flight conditions are assumed to be such that pilots are not able to see and avoid the obstacles. In the event that the calculated collision probability is unacceptable, the procedures specialist may use the CRM to study the relative effects of changes in any of the parameters involved. Examples include removing an obstacle or raising the glide path angle. |   |                         |   |   |   |   | 5 | 6 |   |         |             | airport   |                |        |        |            | x | <ul style="list-style-type: none"> <li>• [ICAO Doc 9274]</li> <li>• [Smith, 1988]</li> <li>• [ACRP 51, 2011]</li> </ul> |   |
| 194. | CRT (Current Reality Tree)                                      | Stat   | Mod       | 1984 | A CRT is a statement of an underlying core problem and the symptoms that arise from it. It maps out a sequence of cause and effect from the core problem to the symptoms. Most of the symptoms will arise from the one core problem or a core conflict. Remove the core problem and we may well be able to remove each of the symptoms as well. Operationally one works backwards from the apparent undesirable effects or symptoms to uncover or discover the underlying core cause.   | Developed by Eliyahu M. Goldratt in his theory of constraints that guides an investigator to identify and relate all root causes using a cause-effect tree whose elements are bound by rules of logic (Categories of Legitimate Reservation). See also Root Cause Analysis.   |                         |   |   |   | 4 |   |   |   |         |             | management, manufacturing   |                |        |        |            |   | x   | <ul style="list-style-type: none"> <li>• [Dettmer, 1997]</li> </ul>                 |

| 195. | CSA<br>(Comparative Safety Assessment)                          | Tab    | Mit     | 2000<br>or<br>older | Each safety hazard is investigated in the context of investment alternatives. The result is a ranking of alternative solutions by reduction in safety risk or other benefits. Steps are to: • Define the alternative solutions under study in system engineering terms (mission, human, machine, media and management); • Develop a set of hierarchical functions that each solution must perform; • Develop a Preliminary Hazard List (PHL) for each alternative solution; • List and evaluate the risk of each hazard for the viable alternative solutions; • Evaluate the risk; • Document the assumptions and justifications for how the severity and probability of each hazard condition was determined.  | The input hazards for CSA are identified in an Operational Safety Assessment (OSA, see ED-78A), which is conducted during Mission Analysis in accordance with the NAS Modernisation System Safety Management Plan (SSMP). A different version of CSA, applicable to food safety (e.g. genetic modifications), was developed in 2003 by Kok & Kuiper.   |                         |   |   |   |   | 5 | 6 |   |         |             | aviation,<br>healthcare,<br>food   | x      |        |        | x          | x   |  | <ul style="list-style-type: none"> <li>• [FAA00] (App B)</li> <li>• [FAA tools]</li> <li>• [Kok &amp; Kuiper, 2003]</li> </ul>  |
| 196. | CSE<br>(Cognitive Systems Engineering)                          | Gen    | HFA     | 1983                | CSE aims at description and analysis of human-machine systems or sociotechnical systems. In CSE the focus is not on human cognition as an internal function or as a mental process, but rather on how cognition is necessary to accomplish effectively the tasks by which specific objectives related to activities can be achieved. CSE proposes that composite operational systems can be looked at as joint cognitive systems. The approach is to observe the field practice and represent the knowledge thus acquired in some form that facilitates the design of appropriate cognitive support systems. Those design solutions are then evaluated via computer modelling or human-in-the-loop simulation. The tools used for knowledge acquisition, knowledge representation and cognitive modelling have been developed specifically to deal with the complex and nonlinear nature of human cognition; its hidden interdependencies and those of its processes that are beyond the conscious awareness of the operational expert. | Formulated by Erik Hollnagel and David Woods. CSE emerged as a research direction in the early 1980s, and has since then grown to become a recognized discipline. CSE addresses the problems of people working with complex systems. Sometimes referred to as Cognitive Engineering.   |                         |   |   |   | 4 |   |   |   |         |             | healthcare,<br>(navy),<br>(nuclear),<br>(aviation),<br>(defence),<br>(ATM) |        |        |        | x          |   |  | <ul style="list-style-type: none"> <li>• [CSE web]</li> <li>• [Gualtieri, 2005]</li> <li>• [Hollnagel &amp; Woods, 1983]</li> <li>• [Hollnagel &amp; Woods, 2005]</li> <li>• [Lintern]</li> </ul> |
| 197. | CSM<br>(Common Safety Method on risk evaluation and assessment) | Int    | OpR     | 2009                | This is a framework process for assessing the risk associated with changes to the railway system, including technical, operational and organisational changes. It follows generic steps, including scope and system definition, hazard identification, identification of scenarios, risk assessment, comparison to criteria, identification of safety measures to mitigate or control the risk, demonstration of compliance. The framework does not prescribe specific techniques to be used for each step.   | The CSM method for risk evaluation and risk assessment makes part of a set of Common Safety Methods (CSMs) established in accordance with Article 6 of European Union Directive 2016/798. The CSMs describe how the safety levels, the achievement of safety targets and compliance with other safety requirements should be fulfilled. Depending on their scope, they are applied by authorities and/or by specific actors of the railway system (e.g. railway undertakings, infrastructure managers, entities in charge of maintenance). | 1                       | 2 | 3 | 4 | 5 | 6 | 7 |   |         | rail        | x  | x      | x      | x      | x          | <ul style="list-style-type: none"> <li>• [ERA CSM web]</li> <li>• [Jovicic, 2009a]</li> <li>• [Jovicic, 2009b]</li> </ul> |  |   |

| 198. | CSP<br>(Communicating Sequential Processes)      | Gen    | Des         | 1978<br>;<br>update in<br>1985 | Formal language for the specification of concurrent software systems, i.e. systems of communicating processes operating concurrently. Allows one to describe systems as a number of components (processes) which operate independently and communicate with each other over well-defined channels.   | First version was described by C.A.R. Hoare. Descriptive tool in cases where a system must consist of more than one process. Related to CCS. The restriction that the component processes must be sequential was removed between 1978 and 1985, but the name was already established. Software requirements specification phase and design & development phase. |                         |   | 3 |   |   |   |   |   |         |             |        |        |        |        |            |  |  | <ul style="list-style-type: none"> <li>• [Bishop, 1990]</li> <li>• [EN 50128, 1996]</li> <li>• [Rakowsky]</li> </ul>        |
| 199. | CSS<br>(Confined Space Safety)                   | Step   | HZA         | 1992                           | The purpose of this analysis technique is to provide a systematic examination of confined space risks. A confined space is defined to be an area that 1) has limited or restricted means of entry or exit; 2) is large enough for a person to enter to perform tasks; 3) and is not designed or configured for continuous occupancy. The analysis includes investigation of hazardous atmospheres, e.g. insufficient ventilation to remove dangerous air contamination and/or oxygen deficiency, or hazardous configurations of the walls of the space.  | Any confined areas where there may be a hazardous atmosphere, toxic fume, or gas, the lack of oxygen, could present risks. Confined Space Safety is applicable to tank farms, fuel storage areas, manholes, transformer vaults, confined electrical spaces, race-ways.  |                         |   | 3 |   |   |   |   |   |         |             |        | x      |        |        |            |  |  | <ul style="list-style-type: none"> <li>• [FAA00]</li> <li>• [ΣΣ93, ΣΣ97]</li> <li>• [OSHA CSS]</li> </ul>                   |
| 200. | CSSA<br>(Cryogenic Systems Safety Analysis)      | Step   | Mit         | 1982                           | The purpose is to specifically examine cryogenic systems from a safety standpoint in order to eliminate or to mitigate the hazardous effects of potentially hazardous materials at extremely low temperatures.   | Use with PHA or SSHA. Cryogenic is a term applied to low-temperature substances and apparatus.  |                         |   | 3 |   |   | 6 |   |   |         |             |        | x      |        |        |            |  |  | <ul style="list-style-type: none"> <li>• [FAA AC431]</li> <li>• [ΣΣ93, ΣΣ97]</li> </ul>                                     |
| 201. | CSSM<br>(Continuous Safety Sampling Methodology) | Stat   | HZA,<br>Mit | 1997                           | This is a form of hazard analysis that uses observation and sampling techniques to determine and maintain a pre-set level of the operator's physical safety within constraints of cost, time, and operational effectiveness. Sampling is performed to observe the occurrence of conditions that may become hazardous in a given system and could result in an accident or occupational disease. The collected data are then used to generate a control chart. Based on the pattern of the control chart, a system "under control" is not disturbed whereas a system "out of control" is investigated for potential conditions becoming hazardous. Appropriate steps are then taken to eliminate or control these conditions to maintain a desired safe system. | Developed by R. Quintana and A. Nair, University of Texas.  |                         |   | 3 | 4 |   | 6 |   |   |         |             |        | x      |        | x      |            |  |  | <ul style="list-style-type: none"> <li>• [HIFA Data]</li> <li>• [FAA HFW]</li> <li>• [Quintana &amp; Nair, 1997]</li> </ul> |

| 202. | CTA<br>(Cognitive Task Analysis) | Gen    | Task    | 1983          | CTA thoroughly describes some aspect of human operation and cognitive processing within a work domain. CTA is used to design human-system interaction and displays, assess job requirements, develop training, or evaluate teamwork. A CTA is an analysis of the knowledge and skills required for a proper performance of a particular task. The framework consists of three elements: (a) an analysis of the task that has to be carried out to accomplish particular goals; (b) an analysis of the knowledge and skills required to accomplish these tasks; and (c) an analysis of the cognitive (thought) processes of experienced and less experienced persons.   | [MIL-HDBK, 1999] describes three examples for conducting CTA: 1) The Precursor, Action, Results and Interpretation method (PARI); 2) Conceptual Graph Analysis (CGA); 3) Critical Decision Method. Tools: GOMS, DNA Method (Decompose, Network, and Assess Method)  |                         |   | 2 |   |   |   |   |   |         |             |        |        |        |        |            | <ul style="list-style-type: none"> <li>• [Davison]</li> <li>• [MIL-HDBK, 1999]</li> <li>• [Mislevy et al, 1998]</li> <li>• [Klein, 2004]</li> <li>• [Kieras, 1988]</li> <li>• [Johnson, 1992]</li> <li>• [Schaaftal &amp; Schraagen, 2000]</li> <li>• [FAA HFW]</li> </ul> |  |
| 203. | CTA<br>(Critical Task Analysis)  | Tab    | Task    | 1979 or older | A Critical Task Analysis aims to describe the results of analyses of critical tasks performed to provide a basis for evaluation of the design of the system, equipment, or facility, verifying that human engineering technical risks have been minimised and solutions are in hand.   | Developed by FAA. Critical tasks are elemental actions required to perform the task. 'Critical' is usually defined as being necessary for mission success.  |                         |   | 2 |   |   |   |   |   |         |             |        |        |        |        |            | <ul style="list-style-type: none"> <li>• [FAA HFW]</li> <li>• [HEAT overview]</li> <li>• [Beevis, 1992]</li> </ul>   |  |
| 204. | CTC<br>(Comparison-To-Criteria)  | Tab    | HZA     | 1993          | The purpose of CTC is to provide a formal and structured format that identifies safety requirements. Any deviations between the existing design requirements and those required are identified in a systematic manner, and the effect of such deviations on the safety of the process or facility is evaluated. The deviations with respect to system upsets are those caused by operational, external, and natural events. Operational events include, among others, individual component failures, human error interactions with the system (to include operation, maintenance, and testing), and support system failures. For systems that do not meet current design requirements, an upgrade is not done automatically until an assessment of their importance to safety is made. | Comparison-To-Criteria is a listing of pertinent safety criteria. This technique can be considered in a Requirements Cross-Check Analysis. Applicable safety-related requirements such as OSHA (Occupational Safety and Health Administration), NFPA (National Fire Protection Association), ANSI (American National Standards Institute), are reviewed against an existing system or facility.   |                         |   |   |   |   |   | 6 | 7 |         |             |        | x      | x      | x      |            | <ul style="list-style-type: none"> <li>• [FAA00]</li> <li>• [McClure &amp; Restrepo, 1999]</li> <li>• [ΣΣ93, ΣΣ97]</li> </ul>  |  |
| 205. | CTD<br>(Cognitive Task Design)   | Gen    | Task    | 1995 or older | The aim of Cognitive Task Design is to focus on the consequences that artefacts have for how they are used, and how this use changes the way we think about them and work with them – on the individual as well as organisational level. The ambition is to ensure that Cognitive Task Design is an explicit part of the design activity, rather than something that is done fortuitously and in an unsystematic manner.   | In some references, e.g. [Sutcliffe, 2003], CTD is presented as a generic term rather than a specific technique. CTD has the same roots as Cognitive Task Analysis (CTA), but the focus is on macro-cognition rather than micro-cognition, i.e., the requisite variety of the joint system, rather than the knowledge, thought processes, and goal structures of the humans in the system. CTD goes beyond CTA, as the emphasis is on the potential (future) rather than the actual (past and present) performance. |                         |   |   |   | 4 |   |   |   |         |             |        |        |        |        |            | <ul style="list-style-type: none"> <li>• [CTD web]</li> <li>• [Hollnagel, 2003]</li> <li>• [Sutcliffe, 2003]</li> <li>• [Worden &amp; Schneider, 1995]</li> </ul>  |  |

| 206. | CWA<br>(Cognitive Work Analysis) | Int    | Task    | 1975 | CWA analyzes the work people do, the tasks they perform, the decisions they make, their information behavior, and the context in which they perform their work - for the purpose of systems design. It offers a mechanism to transfer results from an in-depth analysis of human-information work interaction directly to design requirements. CWA focuses on identifying the constraints that shape behavior rather than trying to predict behavior itself. It consists of five layers of analysis: 1. Work Domain - The functional structure of the work domain in which behavior takes place. 2. Control Tasks - The generic tasks that are to be accomplished. 3. Strategies - The set of strategies that can be used to carry out those tasks. 4. Social-Organisational - The organisation structure. 5. Worker Competencies - The competencies required of operators to deal with these demands. | Cognitive Work Analysis was developed in the 1970s at the Risø National Laboratory in Denmark, to facilitate human-centered design. It complements traditional task analysis by adding the capability of designing for the unanticipated by describing the constraints on behavior rather than behavior per se. Can be used in Cognitive Task design (CTD). |                         | 2 |   |   |   |   |   |   |         |             |        |        |        |        |            | <ul style="list-style-type: none"> <li>• [FAA HFW]</li> <li>• [CWA portal]</li> <li>• [Naikar, 2006]</li> </ul>   |
| 207. | DAD<br>(Decision Action Diagram) | Stat   | Task    | 1950 | Aim is to show how to navigate a system, based on decisions and actions. Actions are drawn as rectangles, decisions as diamonds, and possible decision outcomes are labelled on arrows from decision diamonds. Decisions can be phrased as yes/no or as multiple choice questions.   | Developed by Dunlap & Associates in the 1950s. Similar in appearance and logic to the mechanical handling diagrams which are used in mechanical HAZOPs. Also known as Information Flow Charts or Decision-Action-Information Diagrams. Also similar to functional flow diagrams except that decision points are added.                                      |                         | 2 |   |   |   |   |   |   |         |             |        | x      |        |        |            | <ul style="list-style-type: none"> <li>• [HEAT overview]</li> <li>• [Kennedy &amp; Kirwan, 1998]</li> <li>• [Kirwan, 1994]</li> <li>• [Kirwan &amp; Ainsworth, 1992]</li> <li>• [MIL-HDBK, 1999]</li> <li>• [Silva et al, 1999]</li> <li>• [FAA HFW]</li> <li>• [Beevis, 1992]</li> </ul> |
| 208. | Data Flow Analysis               | Stat   | SwD     | 1973 | Data flow analysis is a static analysis technique that is performed both at procedure level and also as part of the system wide analysis, which is one aspect of integration testing. It identifies data flow anomalies in the program, e.g. the use of uninitialized variables.<br>It gathers information about the possible set of values calculated at various points in a computer program. A program's control flow graph is used to determine those parts of a program to which a particular value assigned to a variable might propagate. The information gathered is often used by compilers when optimizing a program.  | A simple way to perform dataflow analysis of programs is to set up dataflow equations for each node of the control flow graph and solve them by repeatedly calculating the output from the input locally at each node until the whole system stabilizes, i.e., it reaches a fixpoint. See also Control Flow Analysis.                                       |                         |   | 3 |   |   |   |   |   |         |             |        | x      |        |        |            | <ul style="list-style-type: none"> <li>• [EN 50128, 1996]</li> <li>• [Rakowsky]</li> <li>• [SPARK web]</li> </ul>   |

| 209. | Data Mining                    | Min    | Dat     | 1750          | Data Mining is defined as the systematic and automatised searching of a database in order to extract information and patterns. Data mining commonly involves four classes of tasks: <ul style="list-style-type: none"> <li>Clustering - is the task of discovering groups and structures in the data that are "similar", without using known structures in the data.</li> <li>Classification - is the task of generalizing known structure to apply to new data. Common algorithms include decision tree learning, nearest neighbour, naive Bayesian classification, neural networks and support vector machines.</li> <li>Regression - attempts to find a function which models the data with the least error.</li> <li>Association rule learning - searches for relationships between variables.</li> </ul> | Early methods of identifying patterns in data include Bayes' theorem (1700s) and regression analysis (1800s). Some tools are: <ul style="list-style-type: none"> <li>Aviation Safety Data Mining Workbench (MITRE, 2001) - three data mining techniques for application to aviation safety data</li> <li>Brio Intelligence 6 (Brio Software Japan (1999); Hyperion (2003))</li> <li>IMS (Inductive Monitoring System) (NASA Ames, 2003) – Health monitoring</li> <li>QUORUM Perilog (NASA, 1995) – four data mining techniques; supports FAA's Aviation Safety Reporting System (ASRS)</li> </ul> Other tools related to Data Mining are: Mariana, ReADS (Recurring Anomaly Detection System). | 210. | Data Security                  | Gen    | Des     | 1975 or older | Data security is the means of ensuring that data is kept safe from corruption and that access to it is suitably controlled. Thus data security helps to ensure privacy. It also helps in protecting personal data. Aim is to guard against external and internal threats which can either accidentally or deliberately endanger the objectives of design and may lead to unsafe operation.  | Tools available.   |                         |   |   |   |   |   |   | 6 |                                     | finance, electronics, security, defence, social   |        | x      |        |        |   | <ul style="list-style-type: none"> <li>[Bishop, 1990]</li> </ul>   |
| 211. | DBN (Dynamic Bayesian Network) | Dyn    | Mod     | 1997 or older | Dynamic Bayesian Networks (or Dynamic Bayesian Belief Networks) are a method for studying state-transition systems with stochastic behaviour. A DBN is a Bayesian network that represents sequences of variables. These sequences are often time-series (for example, in speech recognition) or sequences of symbols (for example, protein sequences). DBNs comprise a large number of probabilistic graphical models, which can be used as a graphical representation of dynamic systems. With this, they provide a unified probabilistic framework in integrating multimodalities.  | A Dynamic Bayesian Network extends the static Bayesian Belief Network (BBN) by modelling changes of stochastic variables over time. The hidden Markov model and the Kalman filter can be considered as the simplest dynamic Bayesian network.  |                         |   |   | 4 | 5 |   |   |   | healthcare, leisure, road, security | x   | x      | x      | x      | x      | <ul style="list-style-type: none"> <li>[Goransson &amp; Koski, 2002]</li> <li>[Murphy, 2002]</li> </ul> |  |

| 212. | DCA<br>(Design Constraint Analysis)       | Step   | SwD     | 1996<br>or<br>older | Evaluates restrictions imposed by requirements, the real world and environmental limitations, as well as by the design solution. The design materials should describe all known or anticipated restrictions on a software component. These restrictions may include: update timing and sizing constraints; equations and algorithms limitations; input and output data limitations (e.g., range, resolution, accuracy); design solution limitations; sensor/actuator accuracy and calibration; noise; quantization/roundoff noise/errors; actuator power / energy capability; capability of energy storage devices; human factors, human capabilities and limitations; physical time constraints and response times; off nominal environments; friction, inertia, backlash in mechanical systems; validity of models and control laws versus actual system behavior; accommodations for changes of system behavior over time: wear-in, hardware wear-out, end of life performance versus beginning of life performance degraded system behavior and performance. Design constraint analysis evaluates the ability of the software to operate within these constraints. | A constraint is a design target that must be met for the design to be successful. (In contrast, an objective is a design target where more (or less) is better.)   |                         |   |   |   |   |   |   | 6 |         |             | software,<br>(avionics),<br>(space) | x      |        |        |            |  |  | <ul style="list-style-type: none"> <li>• [FAA00]</li> <li>• [NASA-GB-1740.13-96]</li> <li>• [Rakowsky]</li> </ul> |
| 213. | DCPN<br>(Dynamically Coloured Petri Nets) | Dyn    | Mod     | 1997                | Extension of Petri Nets to include dynamic colours, i.e. variables attached to Petri net tokens that can take on real values and that can change through time according to the solutions of (ordinary) differential equations. There are 3 types of transitions: immediate transitions (zero delay), delay transitions (exponential delay) or guard transitions (colours of input tokens reaching certain values).   | DCPN are mathematically equivalent to PDP (Piecewise Deterministic Markov Processes). A DCPN extension to include stochastic differential equations is referred to as SDCPN. DCPN and SDCPN are the main modelling formats used for MA-DRM. See also MA-DRM, see also TOPAZ, see also SDCPN. |                         |   |   |   | 4 | 5 |   |   |         | ATM         | x                                   | x      | x      | x      | x          | <ul style="list-style-type: none"> <li>• [Everdij &amp; Blom &amp; Klompstra, 1997]</li> <li>• [Everdij &amp; Blom, 2003]</li> <li>• [Everdij &amp; Blom, 2005]</li> <li>• [Everdij et al, 2004]</li> <li>• [Everdij, 2010]</li> </ul> |  |   |
| 214. | DD<br>(Dependence Diagrams)               | Stat   | Mod     | 1994<br>or<br>older | Structured, deductive, top-down analysis that identifies the conditions, failures, and events that would cause each defined failure condition. Graphical method of identifying the logical relationship between each particular failure condition and the primary element or component failures, other events, or combinations of these that can cause the failure condition. Similar to FTA, except that a Fault Tree Analysis is failure-oriented and is conducted from the perspective of which failures must occur to cause a defined failure condition. A Dependence Diagram Analysis is success-oriented and is conducted from the perspective of which failures must not occur to preclude a defined failure condition.   | In some references stated to be equivalent to Reliability Block Diagrams (RBD). Also equivalent to Success Trees.  |                         |   |   |   | 4 |   |   |   |         | aircraft    | x                                   |        |        |        |            | <ul style="list-style-type: none"> <li>• [ARP 4761]</li> <li>• [FAA memo02]</li> </ul>   |  |   |

| 215. | DDA<br>(Design Data Analysis)         | Step   | SwD     | 1996 or older | Design data analysis evaluates the description and intended use of each data item in the software design. Data analysis ensures that the structure and intended use of data will not violate a safety requirement. A technique used in performing design data analysis is to compare description-to-use of each data item in the design logic. Interrupts and their effect on data must receive special attention in safety-critical areas. Analysis should verify that interrupts and interrupt handling routines do not alter critical data items used by other routines. The integrity of each data item should be evaluated with respect to its environment and host. Shared memory, and dynamic memory allocation can affect data integrity. Data items should also be protected from being overwritten by unauthorized applications. |   |                         |   |   |   |   | 6 |   |   | software, (avionics), (space)                     | x           |        |        |        |        | <ul style="list-style-type: none"> <li>[FAA00]</li> <li>[NASA-GB-1740.13-96]</li> <li>[Rakowsky]</li> </ul> |
| 216. | DDET<br>(Discrete Dynamic Event Tree) | Dyn    | Mod     | 1988          | DDET is a simulation method implemented by forward branching event trees; the branch points are restricted at discrete times only. The knowledge of the physical system under study is contained in a numerical simulation, written by the analyst. The components of the system are modelled in terms of discrete states. All possible branches of the system evolution are tracked. The events (branches) can only happen at predefined discrete time intervals. It is assumed that if the appropriate time step is chosen, DDETs would investigate all possible scenarios. The systematic branching would easily lead to such a huge number of sequences that the management of the output Event Tree becomes awkward. Measures have been taken to eliminate the explosion.   | DDET is an extension of the classical event trees, by removing the binary logic restriction. The construction of the DDET can be computerized. In order to better manage the multiple generated scenarios by the DDET, methods as DYLAM and DETAM were developed. |                         |   |   | 4 |   |   |   |   | nuclear   | x           |        |        |        |        | <ul style="list-style-type: none"> <li>[Amendola, 1988]</li> <li>[Hu, 2005]</li> </ul>                      |

| 219. | Defensive Programming                                | Gen      | Des     | 1988 or older | Defensive programming is an approach to improve software and source code, in terms of: General quality - Reducing the number of software bugs and problems; Making the source code comprehensible - the source code should be readable and understandable so it is approved in a code audit; Making the software behave in a predictable manner despite unexpected inputs or user actions. Aim is to produce programs which detect anomalous control flow, data flow or data values during their execution and react to these in a predetermined and acceptable manner.  | Useful where there is insufficient confidence in the environment or the software. Tools available. Similar to Failure assertion programming. Software architecture phase.   |                         |   |   | 3 |   |   |   | 6 |         |             |   | software            |        | x      |            |  |   | <ul style="list-style-type: none"> <li>• [Bishop, 1990]</li> <li>• [EN 50128, 1996]</li> </ul>   |
| 220. | Delphi Knowledge Elicitation Method or Delphi Method | Dat, Tab | Dat     | 1959          | The Delphi method allows experts to deal systematically with a complex problem or task. The technique comprises a series of questionnaires sent either by mail or via computerised systems, to a pre-selected group of geographically dispersed experts. These questionnaires are designed to elicit and develop individual responses to the problems posed and to enable the experts to refine their views as the group's work progresses in accordance with the assigned task. The group interaction in Delphi is anonymous; comments, forecasts, and the like are not identified as to their originator but are presented to the group in such a way as to suppress any identification. | Developed by Olaf Helmer, Norman Dalkey, and Nicholas Rescher to forecast the impact of technology on warfare. The name "Delphi" derives from the Oracle of Delphi (Greece), due to its use for forecasting. The main point behind the Delphi method is to overcome the disadvantages of conventional committee action. Anonymity, controlled feedback, and statistical response characterise Delphi. |                         |   |   | 3 |   |   | 5 |   |         |             | defence, finance, healthcare, social, management, aviation, ATM | x                   |        | x      |            |  | <ul style="list-style-type: none"> <li>• [Delphi]</li> <li>• [Rakowsky]</li> <li>• [Cuhls, 2003]</li> </ul> |  |
| 221. | Delta-X Monte Carlo Method                           | FTS      | Par     | 2007          | Delta-X deals with quantifying the error made when low probability cut sets of large fault trees are truncated. Truncation errors are defined by the difference between the actual structure function of a fault tree and the equivalent binary function to the union of all the identified minimal cut sets. For the assessment, Monte Carlo simulation and Importance sampling is used to evaluate the binary functions related to the truncation errors.  | See also HPLV, Monte Carlo Simulation, and Importance Sampling.   |                         |   |   |   |   |   | 5 |   |         |             | (nuclear)   | x                   |        |        |            |  | <ul style="list-style-type: none"> <li>• [ChoiCho, 2007]</li> </ul>   |  |

| 222. | DES (Discrete Event Simulation)   | FTS    | Mod     | 1955          | An event calendar is constructed which indicates what events are scheduled to occur and when. The simulation executes the first event on the calendar, which may lead to a state change, and next updates the calendar.  | See also at Computer Modelling and Simulation. Can be seen as special case of Monte Carlo Simulation, but statements vice versa occur as well.       |                         |   |   |   |   | 4 | 5 |   |         |             |        | healthcare, finance, defence, oil&gas, electronics, manufacturing, management, aviation, airport, nuclear, chemical | x      | x      |            |  |  |  | <ul style="list-style-type: none"> <li>• [MUFTIS3.2-I, 1996]</li> <li>• [Nance, 1993]</li> </ul>   |
| 223. | Design and Coding Standards   | Gen    | Des     | 1994 or older | A Coding Standard aims to avoid potential problems with a programming language before the design is actually implemented in code. The standard can indicate what software constructs, library functions, and other language-specific information must or must not be used. As such, it produces, in practice, a “safe” subset of the programming language. Coding standards may be developed by the software designer, based on the software and hardware system to be used, or may be general standards for a “safer” version of a particular language. | Software design and development phase. See also Code Inspection Checklists. | 226. | DETAM<br>(Dynamic Event Tree Analysis Method) | Dyn    | Mod     | 1991          | DETAM is a generalisation of DYLAM to allow scenario branching based on stochastic variations in operator state. It treats time-dependent evolution of plant hardware states, process variable values, and operator states over the course of a scenario. A dynamic event tree is an event tree in which branchings are allowed at different points in time. This approach is defined by: (a) branching set, (b) set of variables defining the system state, (c) branching rules, (d) sequence expansion rule and (e) quantification tools. The branching set refers to the set of variables that determine the space of possible branches at any node in the tree. Branching rules refer to rules used to determine when a branching should take place (a constant time step). The sequence expansion rules are used to limit the number of sequences. | Developed by Acosta & Siu (MIT Nuclear Engineering Department). This approach can be used to represent operator behaviours, model the consequences of operator actions and also serve as a framework for the analyst to employ a causal model for errors of commission. Thus it allows the testing of emergency procedures and identify where and how changes can be made to improve their effectiveness. |                         |   |   |   | 4 | 5 |   |   |         |             | nuclear                                    | x      |        | x      | x          |   |  | • [MUFTIS3.2-I, 1996]   |
| 227. | Development Standards                         | Gen    | Des     | 1990 or older | To enhance software quality by using standard approaches to the software development process.   | Essential for safety critical systems. Necessary for implementing in a quality assurance program. Tools available. | 228. | DFD<br>(Data Flow Diagrams)                   | Stat   | Mod     | 1979          | Data flow diagrams illustrate how data is processed by a system in terms of inputs and outputs. Different nodes and arrows exist: Processes, Datastores, Dataflows, External entities. DFD can be drawn in several nested layers.   | Developed by Gane and Sarson. The purpose and value of the data flow diagram is primarily data discovery, not process mapping. Several tools exist.   |                         | 2 |   |   |   |   |   |   |         |             | finance, management, social                |        | x      |        |            | x |  | • [AIS-DFD]<br>• [EN 50128, 1996]<br>• [Rakowsky]<br>• [Smartdraw]          |
| 229. | DFM<br>(Double Failure Matrix)                | Tab    | HZA     | 1981          | Inductive approach that considers the effects of double failures. All possible failures are placed on the vertical and the horizontal axis of a matrix, and all combinations are considered and put into severity classes.  | Its use is feasible only for relatively noncomplex systems.   |                         |   |   | 4 | 5 |   |   |   |         |             | space, (nuclear), (defence), (electronics) | x      |        |        |            |   |  | • [FT handbook, 2002]<br>• [MUFTIS3.2-I, 1996]                              |
| 230. | DFM<br>(Dynamic Flowgraph Methodology)        | Int    | SwD     | 1990          | Is an integrated, methodical approach to modelling and analysing the behaviour of software-driven embedded systems for the purpose of dependability assessment and verification. DFM has two fundamental goals: 1) to identify how events can occur in a system; 2) to identify an appropriate testing strategy based on an analysis of system functional behaviour. To achieve these goals, DFM employs a modelling framework in which models expressing the logic of the system being analysed are developed in terms of causal relationships between physical variables and temporal characteristics of the execution of software modules.   | Combines the benefits of conventional SFTA and Petri nets.  |                         |   | 3 | 4 |   |   |   |   |         |             | nuclear, space, (aircraft)                 | x      | x      |        |            |   |  | • [FAA00]<br>• [NASA-GB-1740.13-96]<br>• [Rakowsky]<br>• [Al-Dabbagh, 2009] |

| 231. | DFS Safety Assessment Methodology       | Int    | OpR     | 2001 | Methodology that consists of three major phases: FHA (Functional Hazard Assessment); PSSA (Preliminary System Safety Assessment); SSA (System Safety Assessment). During the FHA, a system's functional structure is analysed, all relevant hazards are identified and assessed according to the severity and conditional probability of their effects. Safety Objectives are defined (quantitative values for the maximum acceptable frequency of a hazard), based on the maximum acceptable frequency of each of the identified effects and the conditional probabilities of the causal links between the hazards and the effects. The PSSA is carried out in order to create Safety Requirements suitable to reach the Safety Objectives. Safety Requirements are concrete specifications for the architecture, the implementation or the operation of the future system. They are derived from the Safety Criticality of a system component, which in turn can be derived from a conditional probabilities assessment. The SSA is performed after the system has been developed and before it goes operational and aims at providing Safety Evidence, i.e. at ensuring that the system is free from unacceptable risks. Besides verifying that all Safety Requirements have been met, the Hazard Analysis performed during FHA and PSSA is refined to reflect new insights and perceptions. All hazards found are classified according to the frequency (or rate) of their occurrence, the actual frequency and the severity of their effects. For every non-acceptable risk found, suitable additional measures or safeguards have to be taken to mitigate that risk. | Developed by DFS (Deutsche FlugSicherung). Main modelling technique used is Bayesian Belief Networks. DFS SAM and EATMP SAM both have further evolved from an old version of EATMP SAM, and by now they are rather different. |                         | 2 | 3 | 4 | 5 | 6 | 7 |                            | ATM     | x           |        | x      | x      |        |                  |  | • [DFS Method Handbook, 2004] |
| 232. | DFT (Design for Testability) (Hardware) | Gen    | Des     | 1948 | DFT is a name for design techniques that add certain testability features to a microelectronic hardware product design. The premise of the added features is that they make it easier to develop and apply manufacturing tests for the designed hardware. The purpose of manufacturing tests is to validate that the product hardware contains no defects that could, otherwise, adversely affect the product's correct functioning. Aim is to enable all hardware components to be fully tested both on and off line.   | Used wherever fault tolerance and redundancy is applied. Tools available.   |                         |   |   |   |   | 6 |   | manufacturing, electronics | x       |             |        |        |        |        | • [Bishop, 1990] |  |                               |

| 233. | DIA<br>(Design Interface Analysis)                       | Step      | SwD     | 1996<br>or<br>older | Verifies the proper design of a software component's interfaces with other components of the system. This analysis will verify that the software component's interfaces as well as the control and data linkages between interfacing components have been properly designed. Interface characteristics to be addressed should include data encoding, error checking and synchronization. The analysis should consider the validity and effectiveness of checksums and CRCs (cyclic redundancy checks). The sophistication of error checking implemented should be appropriate for the predicted bit error rate of the interface. An overall system error rate should be defined, and budgeted to each interface. | Interface requirements specifications are the sources against which the interfaces are evaluated. A checksum is a fixed-size datum computed from an arbitrary block of digital data for the purpose of detecting accidental errors that may have been introduced during its transmission or storage. |                         |   | 3 |   |   |   |   |   |         |             |        |        |        |        |            |  |  |  | <ul style="list-style-type: none"> <li>• [FAA00]</li> <li>• [NASA-GB-1740.13-96]</li> </ul>  |

| 234. | Digraphs   | Stat      | Mod     | 1965<br>or<br>older | A Digraph or Directed Graph consists of vertices (or 'nodes'), connected by directed arcs (arrows). It differs from an ordinary or undirected graph, in that the latter is defined in terms of unordered pairs of vertices, which are usually called edges. Sometimes a digraph is called a simple digraph to distinguish it from a directed multigraph, in which the arcs constitute a multiset, rather than a set, of ordered pairs of vertices. Also, in a simple digraph loops are disallowed. (A loop is an arc that pairs a vertex to itself.) On the other hand, some texts allow loops, multiple arcs, or both in a digraph.   |  |                         |   | 4 |   |   |   |   |   |         |             |        |        |        |        |            |  |  |  | <ul style="list-style-type: none"> <li>• [FAA AC431]</li> <li>• [ΣΣ93, ΣΣ97]</li> <li>• [Bang-Jensen &amp; Gutin, 2007]</li> </ul>                               |

| 235. | Dispersion Modelling or Atmospheric Dispersion Modelling | FTS, Math | Hzi     | 1930                | Dispersion modelling is the mathematical simulation of how air pollutants disperse in the ambient atmosphere. It is performed with computer programs that solve the mathematical equations and algorithms which simulate the pollutant dispersion. The dispersion models are used to estimate or to predict the downwind concentration of air pollutants or toxins emitted from sources such as industrial plants, vehicular traffic or accidental chemical releases.  | Quantitative tool for environmental and system safety engineering. Used in chemical process plants, can determine seriousness of chemical release.   |                         | 2 |   |   |   |   |   |   |         |             |        |        |        |        |            |  |  |  | <ul style="list-style-type: none"> <li>• [Dispersion]</li> </ul>   |
| 236. | Diverse Programming or NVP (N-Version Programming)       | Step      | Des     | 1977                | Diverse Programming (also referred to as N-version programming) involves a variety of routines satisfying the same specification being written in isolation from one another. When a result is sought, voting takes place and the routine giving the most satisfactory answer wins. Aim is to detect and mask residual software design faults during execution of a program in order to prevent safety critical failures of the system, and to continue operation for high reliability.  | Developed by Liming Chen and Algirdas Avizienis. Software architecture phase. Also known as multiversion programming or multiple-version dissimilar software. Useful for safety relevant fault compensating systems.   |                         |   | 3 |   |   |   |   |   |         |             |        |        |        |        |            |  |  |  | <ul style="list-style-type: none"> <li>• [Bishop, 1990]</li> <li>• [EN 50128, 1996]</li> <li>• [Rakowsky]</li> <li>• [SSCS]</li> <li>• [Storey, 1996]</li> </ul> |

| 237. | DLA<br>(Design Logic Analysis)             | Step   | SwD     | 1996<br>or<br>older | DLA evaluates the equations, algorithms and control logic of a software design. Each function performed by a software component is examined. If a function responds to, or has the potential to violate one of the safety requirements, it should be considered critical and undergo logic analysis. In such logic analysis, the safety-critical areas of a software component are examined, design descriptions and logic flows are analysed, and discrepancies are identified.  | An ultimate fully rigorous DLA uses the application of Formal Methods. If this is too costly, then less formal alternative may be used, such as manual tracing of the logic.   |                         |   |   | 3 |   |   |   |   |         |             |        |        |        |        |            |  |  | <ul style="list-style-type: none"> <li>• [FAA00]</li> <li>• [NASA-GB-1740.13-96]</li> <li>• [Rakowsky]</li> </ul>        |
| 238. | DMEA<br>(Damage Mode and Effects Analysis) | Tab    | HZA     | 1977                | Damage Mode and Effects Analysis evaluates the damage potential as a result of an accident caused by hazards and related failures. DMEA expands a FMEA to include data required for vulnerability assessments. Information extracted from an existing FMEA includes: Item identification number; item nomenclature; function; failure modes and causes; mission phase/operation; severity class. DMEA then identifies all possible damage modes which could result from exposure to the specified threat mechanism(s), as well as the consequences of each assumed damage mode on item operation, function and status. Since the damage mode under consideration can affect several indenture levels, the analysis is carried out for local, next higher level and end effects.damage modes, local effects and end effects.   | DMEA is primarily applicable to new or weapon system acquisitions or existing weapon systems. Risks can be minimised and their associated hazards eliminated by evaluating damage progression and severity. Related to and combines with FMEA. |                         |   | 3 | 5 |   |   |   |   |         |             |        |        |        |        |            |  |  | <ul style="list-style-type: none"> <li>• [FAA AC431]</li> <li>• [FAA00]</li> <li>• [ΣΣ93, ΣΣ97]</li> </ul>               |
| 239. | DO-178B<br>(RTCA/EUROCAE ED-12B DO-178B)   | Int    | SwD     | 1981<br>and<br>2011 | International standard on software considerations in airborne systems and equipment certification. Describes issues like systems aspects relating to software development, software lifecycle, software planning, etc, until aircraft and engine certification. The Design Assurance Level (DAL) is determined from the safety assessment process and hazard analysis by examining the effects of a failure condition in the system. The failure conditions are categorized by their effects on the aircraft, crew, and passengers. The categories are: Catastrophic; Hazardous; Major; Minor; No Effect. This software level determines the number of objectives to be satisfied (eventually with independence). The phrase "with independence" refers to a separation of responsibilities where the objectivity of the verification and validation processes is ensured by virtue of their "independence" from the software development team. | Jointly developed by RTCA, Inc. and EUROCAE. First version was released in 1981. Relates to civil aircraft and represents agreement between Europe and US. Updated version (2011) is referred to as DO-178C. See also DO-278.                  |                         | 2 | 3 | 5 | 6 |   |   |   |         |             |        |        |        |        |            |  |  | <ul style="list-style-type: none"> <li>• [DO-178B, 1992]</li> <li>• [DO-178C, 2011]</li> <li>• [Storey, 1996]</li> </ul> |

| 240. | DO-278<br>(RTCA DO-278/EUROCAE ED-109)              | Int    | SwD             | 2002 | RTCA/DO-278 provides guidelines for the assurance of software contained in non-airborne CNS/ATM systems (e.g., surveillance radars, weather radars, navigation systems, surface management systems, air traffic management systems, etc.). The assignment of assurance levels for software is based on the severity and likelihood of system hazards. Design mitigation allows for flexibility in managing system risk that may be influenced by software. Therefore, by translating a specified assurance level from the initial System Risk via the SwAL assignment matrix, an acceptable level of assurance can be specified for the system's software. | DO-278 is the ground based complement to the DO-178B airborne standard. DO-278 was first published in 2002.   |                         |   | 2 | 3 |   |   | 5 | 6 |         |             |  | avionics, ATM |        | x      |            |   |  |   | <ul style="list-style-type: none"> <li>• [SRM Guidance, 2007]</li> <li>• [DO-278A, 2011]</li> </ul> |
| 241. | DODT<br>(Design Option Decision Trees)              | Stat   | HwD<br>,<br>HFA | 1971 | DODT are a means of formally reviewing design options for the human factors implications of design choices. The technique requires a comprehensive understanding of the human factors issues and costs associated with the class of system being developed, together with information on possible technological choices. This requires the equivalent of a "state-of-the-art" review of human factors issues for the particular class of system. The analysis produces a tree of design decisions which have significant human factors costs, and detailed descriptions of the human engineering issues associated with each decision.                     | The original DODT approach was developed by Askren & Korkan (1971) to locate points in the design process for the input of human factors data.  |                         |   |   |   |   | 4 | 5 |   |         |             | manufacturing,<br>(aircraft),<br>(defence) |               | x      |        | x          |   |  | <ul style="list-style-type: none"> <li>• [HEAT overview]</li> <li>• [Beevis, 1992]</li> </ul>     |   |

| 242. | Domino Theory                                       | Gen    | Mit             | 1932 | According to this theory, there are five factors in the accident sequence: 1) the social environment and ancestry; 2) the fault of the person; 3) the unsafe act and/or mechanical or physical hazard; 4) the accident; 5) the injury. These five factors are arranged in a domino fashion such that the fall of the first domino results in the fall of the entire row. This illustrates that each factor leads to the next with the end result being the injury. It also illustrates that if one of the factors (dominos) is removed, the sequence is unable to progress and the injury will not occur.  | Developed by H.W. Heinrich in 1932. Originally used to explain the spread of political ideas through nations around the world. Also referred to as Chain of Multiple Events. | 243. | DOR<br>(Dynamic<br>Observation Report)  | Dat    | Val,<br>Dat | 2001 | This tool allows inspectors to record on-the-spot safety observations outside the planned oversight process. DORs are not intended for routine use as a substitute for planned assessments but are used only in the following situations: a) Single-activity observations unrelated to the FAA ATOS (Air Transportation Oversight System) element being assessed. b) Unplanned observations when there is not an ATOS element or question that addresses the unique situation. c) Unplanned observations about a certificate holder the inspector is not assigned to inspect. d) Observations directed by a handbook bulletin or other national directive.   | See also ConDOR.  |                         |   |   |   |   |   |   |   |         |             | 7      |        | (aviation) | x      |            |                      |   |  |  | <ul style="list-style-type: none"> <li>[FAA FSIMS, 2009]</li> <li>[Sabatini, 2002]</li> </ul> |   |  |
| 244. | DORA<br>(Dynamic<br>Operational Risk<br>Assessment)   | Dyn    | OpR         | 2009 | DORA aims at operational risk analysis in oil/gas and chemical industries, guiding the process design and further optimisation. The probabilistic modelling part of DORA integrates stochastic modelling and process dynamics modelling to evaluate operational risk. The stochastic system-state trajectory is modeled according to the abnormal behavior or failure of each component. For each of the possible system-state trajectories, a process dynamics evaluation is carried out to check whether process variables, e.g., level, flow rate, temperature, pressure, or chemical concentration, remain in their desirable regions. Component testing/inspection intervals and repair times are critical parameters to define the system-state configuration, and play an important role for evaluating the probability of operational failure. |   |                         |   |   |   |   |   |   |   |         |             |        | 4      | 5          |        |            | oil&gas,<br>chemical | x |  |  |   | x | <ul style="list-style-type: none"> <li>[Yanga&amp;Mannan, 2010]</li> </ul> |

| 245. | DREAMS<br>(Dynamic Reliability<br>technique for Error<br>Assessment in Man-<br>machine Systems) | Dyn    | HRA         | 1993 | DREAMS is a DYLAM-related technique for human reliability analysis, which identifies the origin of human errors in the dynamic interaction of the operator and the plant control system. The human behaviour depends on the working environment in which the operator acts ("external world"), and on the "internal world", i.e. his psychological conditions, which are related to stress, emotional factors, fixations, lack of intrinsic knowledge. As a logical consequence of the dynamic interaction of the human with the plant under control, either the error tendency or the ability to recover from a critical situation may be enhanced. Output is an overall probability measure of plant safety related to human erroneous actions.  | Developed by Pietro Cacciabue<br>and others.                      |                         |   |   |   |   |   |   |   |         |             |        |        |            |        | nuclear    |                      |   |  |  | x   |   | <ul style="list-style-type: none"> <li>[MUFTIS3.2-I, 1996]</li> </ul>      |

| 246. | DSA<br>(Deactivation Safety Analysis)                      | Step   | HZA,<br>Mit | 1997<br>or<br>older | This analysis identifies safety and health (S&H) concerns associated with facilities that are decommissioned/closed. The S&H practices are applicable to all deactivation activities, particularly those involving systems or facilities that have used, been used for, or have contained hazardous or toxic materials. The deactivation process involves placing the system or facility into a safe and stable condition that can be economically monitored over an extended period of time while awaiting final disposition for reuse or disposal. The deactivation methodology emphasises specification of end-points for cleanup and stabilisation based upon whether the system or facility will be deactivated for reuse or in preparation for disposal. | Deactivation may include removal of hazardous materials, chemical contamination, spill cleanup.   |                         |   |   | 3 |   |   |   |   |         |             | 7      |   | chemical,<br>nuclear | x      |            |   |  |  |  | <ul style="list-style-type: none"> <li>• [FAA AC431]</li> <li>• [FAA00]</li> <li>• [ΣΣ93, ΣΣ97]</li> </ul> |
| 247. | DTA<br>(Decision Tree Analysis)<br>or<br>Decision Analysis | Stat   | Dec         | 1997                | A decision tree is a decision support tool that uses a tree-like graph or model of decisions and their possible consequences, including chance event outcomes, resource costs, and utility. Decision Trees are tools for helping one to choose between several courses of action. They provide a structure within which one can lay out options and investigate the possible outcomes of choosing those options. They also help to form a balanced picture of the risks and rewards associated with each possible course of action.  | Looks similar to Fault Trees, including the quantification part of FTA. A decision tree can be represented more compactly as an influence diagram, focusing attention on the issues and relationships between events. |                         |   |   |   | 4 | 5 |   |   |         |             |        | nuclear,<br>healthcare,<br>finance, food,<br>security | x                    |        | x          |   |  |  | <ul style="list-style-type: none"> <li>• [MindTools-DTA]</li> <li>• [Straeter, 2001]</li> <li>• [FAA HFW]</li> </ul>   |  |
| 248. | DYLAM<br>(Dynamic Logical Analytical Methodology)          | Dyn    | Mod         | 1985                | Implementation of concept of Dynamic Event Tree Analysis. A physical model for the system is constructed which predicts the response of system process variables to changes in component status. Next, the undesired system states are defined in terms of process variable levels. At the end of the first time interval all possible combinations of component states are identified and their likelihoods are calculated. These states are then used as boundary conditions for the next round of process variable updating. This is continued until an absorbing state is reached.   |   |                         |   |   |   | 4 | 5 |   |   |         |             |        | nuclear,<br>chemical                                  | x                    |        | x          | x |  |  | <ul style="list-style-type: none"> <li>• [Cacciabue &amp; Amendola &amp; Cojazzi8, 1996]</li> <li>• [Cacciabue &amp; Carignano &amp; Vivalda, 1992]</li> <li>• [Cojazzi &amp; Cacciabue, 1992]</li> <li>• [Kirwan, Part 1, 1998]</li> <li>• [MUFTIS3.2-I, 1996]</li> </ul> |  |
| 249. | Dynamic Event Tree Analysis                                | Dyn    | Mod         | 1985                | Couples the probabilistic and physical behaviour of a dynamic process, for more detailed reliability analysis. Presents tree-based representation of an accident scenario.   | See also DYLAM. See also DETAM.   |                         |   |   |   | 4 |   |   |   |         |             |        | nuclear,<br>chemical                                  | x                    |        | x          | x |  |  | <ul style="list-style-type: none"> <li>• [MUFTIS3.2-I, 1996]</li> </ul>  |  |
| 250. | Dynamic Logic  | Dyn    | Des,<br>Mod | 1973<br>or<br>older | Dynamic logic uses a clock signal in its implementation of combinational logic circuits, i.e. logic circuits in which the output is a function of only the current input. The usual use of a clock signal is to synchronize transitions in sequential logic circuits, and for most implementations of combinational logic, a clock signal is not even needed. Aim is to provide self-supervision by the use of a continuously changing signal.   | Desirable in redundant systems as a means of distinguishing faulty channels. Sometimes referred to as Digital Logic or Clocked Logic  |                         |   | 3 |   |   |   |   |   |         |             |        | electronics   |                      | x      |            |   |  |  | <ul style="list-style-type: none"> <li>• [Bishop, 1990]</li> </ul>   |  |

| 252. | EASA CS25.1309, formerly known as JAR-25 (Joint Aviation Requirements Advisory Material Joint (AMJ) 25.1309) | Int    | HwD     | 1974          | JAR-25 provides Joint Aviation Requirements for large (turbine-powered) airplanes. Its Advisory Material Joint (AMJ 25.1309) includes a safety assessment methodology for large airplanes that runs in parallel with the large aeroplane lifecycle stages. The steps are: 1) Define the system and its interfaces, and identify the functions which the system is to perform. Determine whether or not the system is complex, similar to systems used on other aeroplanes, and conventional; 2) Identify and classify the significant failure conditions. This identification and classification may be done by conducting a Functional Hazard Assessment. The procedure depends on whether or not the system is complex; 3) Choose the means to be used to determine compliance with JAR-25.1309 b., c. and d. The depth and scope of the analysis depend on the types of function performed by the system, on the severity of systems failure conditions, and on whether or not the system is complex; 4) Implement the design and produce the data which are agreed with the Certification Authority as being acceptable to show compliance. | First issue was published in 1974. In 1983, the first aircraft was certified to JAR-25. AMJ 25.1309 is used as basis for several other safety assessment methodologies, e.g. ARP 4761, EATMP SAM. ARP 4754 is called up in AMJ 25.1309. Following the establishment of the European Aviation Safety Agency in September 2003 and the adoption of EASA Implementing Rules (IR), Certification Specifications (CS), and Acceptable Means of Compliance and Guidance Material (AMC), the JAA Committee made the decision that in future the JAA would publish amendments to the airworthiness JARs by incorporation of reference to EASA IR, AMC and CS. USA version of JAR-25 is FAR-25, which was issued before JAR-25 as a derivation of older regulations, and does not limit to turbine-powered aeroplanes. |                         | 2 | 3 | 4 | 5 | 6 | 7 |   |                   | aircraft    | x      |        |        |        |            |  |  | <ul style="list-style-type: none"> <li>• [JAR 25.1309]</li> <li>• [Klompstra &amp; Everdij, 1997]</li> <li>• [EASA CS-25, 2012]</li> </ul> |
| 253. | EASp EME 1.1 Method (European Aviation Safety plan Method to Assess Future Risks)                            | Int    | OpR     | 2012          | This method aims at prospective analysis of aviation safety risks. Steps are: 1) Scope the system and the assessment; 2) Describe/model the system and nominal operations; 3) Identify hazards; 4) Combine hazards into a risk framework; 5) Assess and evaluate risks; 6) Identify potential risk controls and reassess residual risk until acceptable; 7) Safety monitoring and verification; 8) Organisational learning and process improvement.   | The eight steps are taken from [SAP 15], enriched with elements from FAST Method, such as use of Areas of Change (AoC), and a selection of methods from this Safety Methods Database.   | 1                       | 2 | 3 | 4 | 5 | 6 | 7 | 8 | (aviation), (ATM) | x           |        |        |        | x      |            |  | <ul style="list-style-type: none"> <li>• [EASp EME1.1, 2012]</li> </ul>  |  |
| 254. | EATMP SAM (European Air Traffic Management Programme Safety Assessment Methodology)                          | Int    | OpR     | 2000 from     | Safety Assessment Methodology supported by EATMP. Consists of three steps: FHA (Functional Hazard Assessment), PSSA (Preliminary System Safety Assessment) and SSA (System Safety Assessment) which run parallel to all development stages of a lifecycle of an Air Navigation System. Each step consists of several substeps.  | Developed by a SAM Task Force chaired by Eurocontrol. Is used widely throughout Europe by Air Navigation Service Providers. The steps FHA, PSSA and SSA are described separately in this database. Version 2.1 was released in 2008.  | 1                       | 2 | 3 | 4 | 5 | 6 | 7 |   | ATM               | x           | x      | x      | x      |        |            |  | <ul style="list-style-type: none"> <li>• [EHQ-SAM, 2002]</li> <li>• [Review of SAM techniques, 2004]</li> </ul>                                |  |

Aimed at identifying organizational and management factors concerning the failure causes. Steps are: Cause complexes are classified and quantified due to their frequencies; Events are assigned weights related to cause complexes; Events are given relevance weights in relation with plant safety; The final score is decided by multiplying the two weights scores.  |  |                         |   |   |   |   |   |   |   | 8       | nuclear     |   |        |        |        |            |  |  | • [Mkrtyan & Turcanu, 2012]  |
| 256. | ECCAIRS<br>(European Co-Ordination Centre for Aviation Incident Reporting Systems) | Dat    | Dat     | 2004          | ECCAIRS is a European Union initiative to harmonise the reporting of aviation occurrences by Member States so that the Member States can pool and share data on a peer-to-peer basis. The proposed data sharing has not yet been implemented. Each Member State will enforce the procedures for collecting and processing the reports. The reports will be placed in an electronic database together with safety relevant information derived from confidential reporting. An electronic network will allow any CAA or AAIB in the EU to have access to the integrated information. It will facilitate independent analyses and plans include having tools for trend and other analysis tools built-in. | Developed by the JRC in Italy. In use in ICAO since 1 January 2004.  |                         |   |   |   |   |   |   |   |         | 8           | aviation                                | x      | x      | x      | x          |  |  | • [GAIN ATM, 2003]<br>• [JRC ECCAIRS]                                  |
| 257. | ECFC<br>(Event and Causal Factor Charting)   | Stat   | Ret     | 1995 or older | Event and Causal Factor Charting utilises a block diagram to graphically display an entire event. The heart of the ECFC is the sequence-of events line. It provides a means to organise the data, provides a summary of what is known and unknown about the event, and results in a detailed sequence of facts and activities. Elements in the charts are: Condition (Ovals), Event (Blocks), Accident, Primary event line, Primary events and conditions, Secondary event lines, Secondary events and conditions, Causal factors, Items of note.   | The technique aims at understanding the sequence of contributing events that lead to an accident.  |                         |   |   |   | 4 |   |   |   |         |             | nuclear, chemical, oil&gas, environment | x      |        |        |            |  |  | • [FAA00]<br>• [ΣΣ93, ΣΣ97]<br>• [OSHAcademy]<br>• [PPI, 2006]         |
| 258. | ECOM<br>(Extended Control Model)   | Stat   | Mod     | 2003          | ECOM acknowledges that the performance of the joint system can be described as involving different but simultaneous layers of control (or concurrent control loops). Some of these are of a closed-loop type or reactive, some are of an open-loop type or proactive, and some are mixed. Additionally, it is acknowledged that the overall level of control can vary, and this variability is an essential factor with regard to the efficiency and reliability of performance. Four layers are defined: Tracking, Regulating, Monitoring, Targeting. The ECOM describes the performance of the joint system by means of four interacting and simultaneous control loops, one for each layer.          | Link with COCOM, which can be seen as an elaboration of the basic cyclical model with emphasis on the different control modes, i.e., how control can be lost and regained, and how the control modes affect the quality of performance. ECOM adds a modelling layer. The degree of control can still be considered relative to the levels of the ECOM. |                         |   |   |   | 4 |   |   |   |         |             | (nuclear), (road)                       |        |        |        | x          |  |  | • [ECOM web]<br>• [Hollnagel & Nabo & Lau, 2003]<br>• [Engstrom, 2006] |

The EMS is a configurable and adaptable Windows 2000 based flight data analysis system. It is capable of managing large bodies of flight data, and can expand with fleet size and changing analysis needs. As the operations grow, EMS has the capacity to continue to extract maximum analysed value from the flight data.  | Developed by Austin Digital.  |                         |   |   |   |   |   |   |   |         | 7           |        | aviation   | x      | x      |            |  |   |   |  | <ul style="list-style-type: none"> <li>• [GAIN AFSA, 2003]</li> </ul>                                      |
| 267. | ENEL approach (Entity for Electricity approach)          | Tab    | Org     | 2006          | Safety culture self-assessment within a nuclear facility, using a questionnaire based on the following principles: Everyone is personally responsible for nuclear safety, Leaders demonstrate commitment to safety, Trust permeates the organization, Decision-making reflects safety first, Nuclear technology is recognized as special and unique, A questioning attitude is cultivated, Organizational learning is embraced, Nuclear safety undergoes constant examination.   |   |                         |   |   |   |   |   |   |   |         | 8           |        | nuclear  |        |        |            |  |   | x |  | <ul style="list-style-type: none"> <li>• [Mkrtychyan &amp; Turcanu, 2012]</li> </ul>                       |
| 268. | Energy Analysis  | Step   | HZA     | 1972 or older | The energy analysis is a means of conducting a system safety evaluation of a system that looks at the “energetics” of the system.  | The technique can be applied to all systems, which contain, make use of, or which store energy in any form or forms, (e.g. potential, kinetic mechanical energy, electrical energy, ionising or non-ionising radiation, chemical, and thermal.) This technique is usually conducted in conjunction with Barrier Analysis and is similar to the Energy Trace part of ETBA. |                         |   |   | 3 |   |   |   |   |         |             |        | chemical, nuclear, police, road, (rail)  | x      |        |            |  |   |   |  | <ul style="list-style-type: none"> <li>• [FAA00]</li> <li>• [ΣΣ93, ΣΣ97]</li> </ul>                        |

|      |   |        |         |               |  |   | 1                       | 2 | 3 | 4 | 5 | 6 | 7 | 8 |         | H<br>w      | S<br>w      | H<br>u                                      | P<br>r | O<br>r |            |   |   |  |  |
| 269. | Energy Trace Checklist  | Tab    | HZI     | 1972 or older | The analysis aids in the identification of hazards associated with energetics within a system, by use of a specifically designed checklist. The use of a checklist can provide a systematic way of collecting information on many similar exposures.   | Similar to ETBA (Energy Trace and Barrier Analysis), to Energy Analysis and to Barrier Analysis. The analysis could be used when conducting evaluation and surveys for hazard identification associated with all forms of energy. |                         |   |   | 3 |   |   |   |   |         |             |             | (chemical),<br>(defence)                    | x      |        |            |   |   |  | <ul style="list-style-type: none"> <li>• [FAA00]</li> <li>• [ΣΣ93, ΣΣ97]</li> </ul>            |
| 270. | Environment Analysis  | Gen    | HZI     | 1997          | Describes the environment in which the activities or basic tasks are performed, with the purpose to identify environment specific factors impacting the task(s).   |   |                         | 2 |   |   |   |   |   |   |         |             |             | no-domain-found                             | x      |        | x          |   |   |  | <ul style="list-style-type: none"> <li>• [FAA HFW]</li> <li>• [Wickens et al, 1997]</li> </ul> |
| 271. | EOCA (Error of Commission Analysis)                                 | Tab    | HRA     | 1995          | HAZOP-based approach whereby experienced operators consider procedures in detail, and what actions could occur other than those desired. Particular task formats, error mode keywords, and PSF (Performance Shaping Factors) are utilised to structure the assessment process and to prompt the assessors. Identified significant errors are then utilised in the PSA fault and/or event trees.  |   |                         |   | 3 |   |   |   |   |   |         |             |             | road, social,<br>(nuclear),<br>(healthcare) | x      | x      | x          | x | x   | <ul style="list-style-type: none"> <li>• [Kirwan, 1994]</li> <li>• [Kirwan, Part 1, 1998]</li> </ul> |  |
| 272. | E-OCVM (European Operational Concept Validation Methodology)        | Int    | Val     | 2007          | E-OCVM includes three aspects of validation that, when viewed together, help provide structure to an iterative and incremental approach to concept development and concept validation: (1) The Concept Lifecycle Model facilitates the setting of appropriate validation objectives and the choice of evaluation techniques, shows how concept validation interfaces with product development and indicates where requirements should be determined; (2) The Structured Planning Framework facilitates programme planning and transparency of the whole process; (3) The Case-Based Approach integrates many evaluation exercise results into key 'cases' (safety case, business case, environment case, human factors case) that address stakeholder issues about air traffic management (ATM) performance and behaviours. These three aspects fit together to form a process. This process is focused on developing a concept towards an application while demonstrating to key stakeholders how to achieve an end system that is fit for purpose. | Developed by Eurocontrol, building on several European Validation project results. See also SARD.   | 1                       | 2 | 3 | 4 | 5 | 6 | 7 | 8 |         |             |             | ATM   | x      | x      | x          | x | x   | <ul style="list-style-type: none"> <li>• [E-OCVM]</li> </ul>   |  |
| 273. | EPA Methods (Environmental Protection Agency Collection of Methods) | Gen    | HZA     | 1991 ?        | Collection of methods for measuring the presence and concentration of chemical pollutants; evaluating properties, such as toxic properties, of chemical substances; or measuring the effects of substances under various conditions. The methods are organised in categories: Air and Radiation; Water; Prevention, Pesticides, and Toxic Substances; Research and Development; Solid Waste and Emergency Response.  | Maintained by Environmental Protection Agency, U.S.A.   |                         |   | 3 | 4 |   |   |   |   |         |             | environment |   |        |        |            | x | <ul style="list-style-type: none"> <li>• [EPA Methods]</li> </ul> |  |  |

| 274. | EPI DCT<br>(Element Performance Inspection Data Collection Tool) | Dat    | Val.<br>HzI      | 1999<br>or<br>older | This tool is for Performance Assessments (PA). It is designed to collect data to help the certification project manager (CPM) or principal inspector (PI) determine if an air carrier adheres to its written procedures and controls for each system element, and if the established performance measures for each system element are met. The PI or CPM needs to determine how many EPI DCTs to complete to obtain the data needed to assess air carrier performance for each element. Typically, an inspector has only one EPI assigned for a specific PA. He or she may complete multiple activities as part of that single EPI. PIs or CPMs may assign EPIs to more than one inspector in a PA. For example, PIs or CPMs may want to assign EPIs to different inspectors for each aircraft fleet, for certain geographic areas, or for different training programs. |  |                         |   |   |   |   |   |   |   | 7       |             | aviation       | x      |        |        |            |  | x | <ul style="list-style-type: none"> <li>[FAA FSIMS, 2009]</li> <li>[GAO, 1999]</li> </ul>   |
| 275. | EPIC<br>(Executive Process Interactive Control)                  | RTS    | HFA<br>,<br>Task | 1994                | EPIC is a cognitive architecture model of human information processing that accounts for the detailed timing of human perceptual, cognitive, and motor activity. EPIC provides a framework for constructing and synthesising models of human-system interaction that are accurate and detailed enough to be useful for practical design purposes. Human performance in a task is simulated by programming the cognitive processor with production rules organized as methods for accomplishing task goals. The EPIC model then is run in interaction with a simulation of the external system and performs the same task as the human operator would. The model generates events (e.g. eye movements, key strokes, vocal utterances) whose timing is accurately predictive of human performance.  | Developed by David E. Kieras and David E. Meyer at the University of Michigan. Takes into account the age of the individual. |                         |   | 2 |   |   |   |   |   |         |             | social, (navy) |        |        |        | x          |  |   | <ul style="list-style-type: none"> <li>[Kieras &amp; Meyer, 1997]</li> <li>[FAA HFW]</li> <li>[Leiden et al., 2001]</li> <li>[Morrison, 2003]</li> </ul> |
| 276. | EPOQUES  | Int    | Mit              | 2002                | EPOQUES is a collection of methods and tools to treat safety occurrences at air traffic service providers. Participatory design and iterative prototyping are being used to define a set of investigative tools. Two complementary methods are being conducted in parallel. One is to study the existing work practices so that the initial prototype is grounded in current every day use. The second is to involve participants and designers to work together to iterate, refine, and extend the design, using rapid prototyping and collective brainstorming.   | Developed at CENA, France.   |                         |   |   |   |   |   |   | 6 |         |             | (ATM)          | x      |        | x      | x          |  |   | <ul style="list-style-type: none"> <li>[GAIN ATM, 2003]</li> <li>[Gaspard, 2002]</li> </ul>  |

| 277. | Equivalence Partitioning and Input Partition Testing | Step   | SwD      | 1995 or older | Software Testing technique. Aim is to test the software adequately using a minimum of test data. The test data is obtained by selecting the partitions of the input domain required to exercise the software. This testing strategy is based on the equivalence relation of the inputs, which determines a partition of the input domain. Test cases are selected with the aim of covering all the partitions previously identified. At least one test case is taken from each equivalence class.   | Also called Equivalence Class Partitioning (ECP). See also Software testing. See also Partitioning.   |                         |   |   |   |   |   |   |   |         |             |        |        |        |        |            |  | <ul style="list-style-type: none"> <li>• [EN 50128, 1996]</li> <li>• [ISO/IEC 15443, 2002]</li> <li>• [Rakowsky]</li> </ul>                         |
| 278. | ER (External Risk)                                   | Math   | OpR      | 1995          | Determination of the third party risk in terms of individual (IR) and societal risk (SR) for the surroundings of airports to individuals induced by air traffic. Quantification of the likelihood to die due to an aircraft accident. Comprises local accident ratio determination, accident location distribution and accident consequences. The latter taking into account consecutive effects such as interaction with dangerous plants and alike. Both traffic level and infrastructure layout form individual scenarios for which IR and SR figures can be computed and graphically displayed. Intended to support procedure design and allow to increase the stakeholder's situational awareness to bottlenecks and to judge new concepts.  | Tool used mainly by airport operators   |                         |   |   |   |   |   | 5 |   |         |             |        |        |        |        |            |  | <ul style="list-style-type: none"> <li>• [GfL web]</li> <li>• [GfL, 2001]</li> <li>• [TUD, 2005]</li> </ul>   |
| 279. | ERA (Environmental Risk Analysis)                    | Step   | HZA      | 1975          | The analysis is conducted to assess the risk of environmental non-compliance that may result in hazards and associated risks. The analysis may include the following steps: 1) Establish the context for the risk assessment process; 2) Identify environmental risks; 3) Analyse risks; 4) Evaluate risks to determine significant issues.   | The analysis is conducted for any system that uses, produces or transports toxic hazardous materials that could cause harm to people and the environment. |                         |   |   | 3 |   |   | 5 |   |         |             |        |        |        |        |            |  | <ul style="list-style-type: none"> <li>• [FAA00]</li> <li>• [ΣΣ93, ΣΣ97]</li> <li>• [Lerche&amp;Paleologos, 2001]</li> <li>• [ERA, 2000]</li> </ul> |
|      | ERC (Event Risk Classification)                      |        |          |               |   | See ARMS  |                         |   |   |   |   |   |   |   |         |             |        |        |        |        |            |  |   |
| 280. | ERCs (European Risk Classification Scheme)           | Tab    | Dec, Ret | 2017          | Aims to provide a standardised methodology for classifying the risk posed by occurrences in aviation. Looks at which barriers have succeeded in ensuring the occurrence did not result in an actual accident. If the risk is beyond a threshold, a more detailed risk assessment is done. The ERCs is a matrix with 5 rows and 11 columns, where the 5 rows show various severity classes. The cells are coloured green, yellow or red. The size of the aircraft involved in the occurrence and the type of occurrence (e.g. mid-air collision, runway excursion), determines which row to look into: Large aircraft and more potential fatalities => top rows; Small aircraft and few fatalities => bottom rows. Next the failure or success of respective barriers determines which column to look into. If many barriers have failed go further to the right; there is another scheme to assist in this process. | Development was mandated by EU Regulation 376/2014 and was tasked to EASA from the European Commission in late 2014. See also RCS                         | 1                       |   |   |   |   |   |   |   |         |             |        |        |        |        |            |  | <ul style="list-style-type: none"> <li>• [EU 376/2014]</li> <li>• [EU 2020/2034]</li> </ul>   |

| 281. | Ergonomics Checklists                | Tab    | Task    | 1949 or older | These are checklists, which an analyst can use to ascertain whether particular ergonomics are being met within a task, or whether the facilities that are provided for that task are adequate.  | See also Checklist Analysis, AET.  |                         |   |   |   |   |   |   |   |         | 7           |        | nuclear, ergonomics, oil&gas, healthcare, manufacturing | x      |        |            |  |  |  | • [Kirwan & Ainsworth, 1992]                                      |
| 282. | ERP (Efficient Risk Priority Number) | Step   | HZA     | 2013          | ERP aims to enhance FMECA by calculating for each hazard $ERP = S \times O \times D \times P \times E / C$ , with S: Severity (severity of consequences); O: Occurrence (probability of occurrence); D: Detection (probability of detection); P: Prevention (extent to which prevention action is possible); E: Effectiveness (extent to which the preventive actions are effective); C: Cost (cost of preventive actions). Hazards with the highest ESPN are addressed first.  |  |                         |   |   |   |   |   |   |   |         | 5           |        | (manufacturing )  | x      |        |            |  |  |  | • [Falcon et al., 2013]   |
| 283. | Error Detection and Correction       | Step   | Des     | 150 AD        | Aim is to detect and correct errors in sensitive information. Describes how to transit bits over a possibly noisy communication channel. This channel may introduce a variety of errors, such as inverted bits and lost bits.   | Method has been used for many centuries, e.g. for precise copying of the bible. May be useful in systems where availability and response times are critical factors. |                         |   |   |   |   |   |   |   |         | 6           |        | electronics, security                                   |        | x      |            |  |  |  | • [Bishop, 1990]<br>• [EN 50128, 1996]<br>• [Rakowsky]            |
| 284. | Error Guessing                       | Step   | HZI     | 1995 or older | Error Guessing is the process of using intuition and past experience to fill in gaps in the test data set. There are no rules to follow. The tester must review the test records with an eye towards recognising missing conditions. Two familiar examples of error prone situations are division by zero and calculating the square root of a negative number. Either of these will result in system errors and garbled output.  | Said to be not repeatable.   |                         |   |   |   |   |   |   |   |         | 3           |        | software  |        | x      |            |  |  |  | • [EN 50128, 1996]<br>• [Rakowsky]                                |
| 285. | Error Message Guidelines             | Gen    | Des     | 1992          | The rules are: Be as specific and precise as possible; Be positive: Avoid Condemnation; Be constructive: Tell user what needs to be done; Be consistent in grammar, terminology, and abbreviations; Use user-centred phrasing; Use consistent display format; Test the usability of error messages; Try to reduce or eliminate the need for error messages.   |  |                         |   |   |   |   |   |   |   |         | 6           |        | software  |        | x      | x          |  |  |  | • [EMG]<br>• [FAA HFW]<br>• [Liu, 1997]<br>• [Schneiderman, 1992] |
| 286. | Error Seeding                        | Step   | SwD     | 1989 or older | Technique that can be used to evaluate the ability of language processors to detect and report errors in source programs. Typical faults are inserted (seeded) into the software. If during testing, K of the N inserted faults are found, then this method assumes that the same percentage of the actual faults are found as well.  | See also Software testing.   |                         |   |   |   |   |   |   |   |         | 7           |        | software  |        | x      |            |  |  |  | • [EN 50128, 1996]<br>• [Meek & Siu, 1989]<br>• [Rakowsky]        |
| 287. | ESA (Explosives Safety Analysis)     | Step   | HZA     | 1970          | This method enables the safety professional to identify and evaluate explosive hazards associated with facilities or operations. The purpose is to provide an assessment of the hazards and potential explosive effects of the storage, handling or operations with various types of explosives from gram to ton quantities and to determine the damage potential. Explosives Safety Analysis can be used to identify hazards and risks related to any explosive potential, i.e. fuel storage, compressed gases, transformers, batteries. | See also SAFER. See also Process Hazard Analysis.  |                         |   |   |   |   |   |   |   |         | 3           |        | chemical, defence                                       | x      |        |            |  |  |  | • [FAA AC431]<br>• [FAA00]<br>• [ΣΣ93, ΣΣ97]<br>• [DDESB, 2000]   |

| 288. | ESAT<br>(Expertensystem zur Aufgaben-Taxonomie (Expert-System for Task Taxonomy)) | Int    | Task    | 1992        | Artificial intelligence concepts are used to describe the human tasks. Quantification of PSF (Performance Shaping Factors) for any task. Determination of a dependability class (from 1-10) by ratings of default PSFs. The functional context between HEP and dependability class is partly given by expert judgement (based on generic cognition of human performance) and partly by measurement of performance.  | Method established in the aviation field (e.g. design of cockpit displays).  |                         | 2 |   |   | 5 |   |   |   |         |             | (aviation)   |        |        | x      |            |   |   |   | • [Straeter, 2001] |
| 289. | ESCAPE<br>(Eurocontrol Simulation Capability Platform for Experimentation)        | RTS    | Trai    | 1996        | ESCAPE is an ATC real-time simulator platform. It uses the Raptor 2500 FPS display technology, using LCD flat panel displays, each with a 170-degree viewing angle. ESCAPE has the capability to simulate a host of different en route scenarios.   | ESCAPE has been developed by EEC and was launched in 1996.   |                         |   |   |   |   |   |   | 7 |         |             | (ATM)  |        |        |        | x          | x |   |   | • [GAIN ATM, 2003] |
| 290. | ESD<br>(Event Sequence Diagrams)  | Stat   | Mod     | 1983        | An event-sequence diagram is a schematic representation of the sequence of events leading up until failure. In other words, it is a flow chart with a number of paths showing the 'big picture' of what happened - a holistic view. ESD can be used to identify pivotal events or defenses to prevent the progression of accident scenarios to undesired end states. It is a variation of Cause Consequence Diagram and generalisation of ETA, not restricted to representation of event sequences, repairable systems can be modelled. | First used by Pickard, Lowe and Garrick in 1983; extended and mathematically formulated by Swaminathan and Smidts in 1999.   |                         |   |   | 4 |   |   |   |   |         |             | nuclear, aviation, space                                     | x      |        | x      | x          |   |   | • [MUFTIS3.2-I, 1996]<br>• [Swaminathan & Smidts, 1999]   |                    |
| 291. | ESSAI<br>(Enhanced Safety through Situation Awareness Integration in training)    | Int    | Trai    | 2000 - 2002 | The ESSAI project developed a training approach for problems that occur in cockpits when pilots are confronted with extreme situations (a Crisis) for which they do not have appropriate procedures. These extreme situations may be the result of a rare chain of events, but may also occur because of lack of Situation Awareness of the crew. The project plans to develop training tools and techniques and their implementation in training programmes.   |  |                         |   |   |   |   | 6 |   |   |         |             | (aviation)   |        |        |        | x          | x | x | • [ESSAI web]<br>• [Hörmann et al, 2003]  |                    |
| 292. | ETA<br>(Event Tree Analysis)  | Stat   | Mod     | 1968        | An Event Tree models the sequence of events that results from a single initiating event and thereby describes how serious consequences can occur. Can be used for developing counter measures to reduce the consequences. The tool can be used to organise, characterise, and quantify potential accidents in a methodical manner. The analysis is accomplished by selecting initiating events, both desired and undesired, and develop their consequences through consideration of system/component failure-and-success alternatives.  | Former name is CTM (Consequence Tree Method). Useful in conjunction with fault tree analysis as an alternative to cause-consequence diagrams. Mainly for technical systems; human error may also be modelled. Tools available, e.g. Fault Tree+, RISKMAN, see [GAIN AFSA, 2003]. A variation developed for error of commission analysis is GASET (Generic Accident Sequence Event Tree). |                         |   |   | 4 | 5 |   |   |   |         |             | nuclear, healthcare, aircraft, ATM, oil&gas, space, chemical | x      |        | x      | x          |   |   | • [Leveson, 1995]<br>• [MUFTIS3.2-I, 1996]<br>• [Rakowsky] claims this one does handle software<br>• [ΣΣ93, ΣΣ97]<br>• [Baybutt, 1989]<br>• [DNV-HSE, 2001]<br>• [Rademakers et al, 1992]<br>• [Rakowsky]<br>• [Reason, 1990]<br>• [Siu, 1994]<br>• [Smith, 1996 and 1997]<br>• [Storey, 1996]<br>• [Terpstra, 1984]<br>• [Villemeur, 1991] |                    |

| 293. | ETBA<br>(Energy Trace and Barrier Analysis)                           | Step   | HzA     | 1973 | The analysis aims to produce a consistent, detailed understanding of the sources and nature of energy flows that can or did produce accidental harm. The ETBA method is a system safety-based analysis process developed to aid in the methodical discovery and definition of hazards and risks of loss in systems by producing a consistent, detailed understanding of the sources and nature of energy flows that can or did produce accidental harm. Outputs support estimation of risk levels, and the identification and assessment of specific options for eliminating or controlling risk. These analyses are routinely started in conjunction with the System Hazard Analysis and may be initiated when critical changes or modifications are made.   | ETBA is similar to Energy Analysis and to Barrier Analysis. The technique can be applied to all systems, which contain, make use of, or which store energy in any form or forms, (e.g. potential, kinetic mechanical energy, electrical energy, ionising or non-ionising radiation, chemical, and thermal.) Developed as part of MORT. |                         |   |   | 3 |   | 5 | 6 |   |         |             | chemical, nuclear, police, road, (rail) | x      |        |        |            |   |   | <ul style="list-style-type: none"> <li>• [FAA AC431]</li> <li>• [FAA00]</li> <li>• [ΣΣ93, ΣΣ97]</li> </ul> |
| 294. | ETTO<br>(Efficiency-Thoroughness Trade-Off)                           | Gen    | Mod     | 2002 | ETTO is a principle that concludes that both normal performance and failures are emergent phenomena, hence that neither can be attributed to or explained by specific components or parts. For the humans in the system this means in particular that the reason why the outcome of their actions differs from what was intended or required, is due to the variability of the context and conditions rather than to the failures of actions. The adaptability and flexibility of human work is the reason for its efficiency. At the same time it is also the reason for the failures that occur, although it is never the cause of the failures. Herein lies the paradox of optimal performance at the individual level. If anything is unreasonable, it is the requirement to be both efficient and thorough at the same time – or rather to be thorough when with hindsight it was wrong to be efficient. |  |                         |   |   |   | 4 |   |   |   |         |             | (healthcare), (nuclear)                 |        |        | x      |            |   | <ul style="list-style-type: none"> <li>• [Hollnagel-ETTO]</li> <li>• [Hollnagel, 2004]</li> </ul> |  |
| 295. | European Air Navigation Service Providers (ANSPs) Safety Culture Tool | Tab    | Org     | 2006 | Aim is to assess the safety culture of an air traffic management organization. Uses questionnaires, interviews and workshops to discuss: Commitment to safety; Resources for safety; Responsibility for safety; Involving air traffic controllers in safety; Management involvement in safety; Teaming for safety; Reporting incidents/communicating problems; Learning from incidents; Blame and error tolerance/discipline and Punishment; Communication about procedural/system changes; Trust within the organization; Real working practices; Regulatory effectiveness.  |  |                         |   |   |   |   |   |   |   | 8       | ATM         |   |        |        |        |            | x | <ul style="list-style-type: none"> <li>• [Mkrtychyan &amp; Turcanu, 2012]</li> </ul>              |  |

| 296. | Expert Judgement   | Gen    | Par     |               | Generic term for using human expert judgement for providing qualitative or quantitative information in safety assessments. Several expert judgement techniques exist, such as APJ or PC.   | Expert judgement is often used, especially where statistical data is scarce, but needs to be treated with special care. There are well-proven protocols for maximising and testing its validity. |                         |   |   |   |   |   |   |   |         |               |        |        |        |        |            | <ul style="list-style-type: none"> <li>• [Ayyub, 2001]</li> <li>• [Humphreys, 1988]</li> <li>• [Kirwan, 1994]</li> <li>• [Kirwan &amp; Kennedy &amp; Hamblen]</li> <li>• [Nijstad, 2001]</li> <li>• [Williams, 1985]</li> <li>• [Basra &amp; Kirwan, 1998]</li> <li>• [Foot, 1994]</li> <li>• [MUFTIS3.2-I, 1996]</li> <li>• [FAA HFW]</li> </ul> |   |
| 297. | Ex-Post Facto Analysis   | Min    | Ret     | 1980 or older | Is employed to study whether a causal relationship may exist. Statistics on accidents are compared with similar statistics for accident-free situations. The aim is to identify factors which are more common in the accident material than what is expected because of pure chance. In the next step, physical, physiological and psychological theories are brought in to explain the actual causal relationships.   |  |                         |   | 3 | 4 |   |   |   |   |         |               |        |        |        |        |            | <ul style="list-style-type: none"> <li>• [Kjellen, 2000]</li> </ul>   |   |
| 298. | FACE (Framework for Analysing Commission Errors)                     | Int    | HRA     | 1999          | Framework for analysing errors of commission. The framework consists of five generic phases: I) Target selection, II) identification of potential commission opportunities, III) screening commission opportunities, IV) modelling important commission opportunities, V) probability assessment.  |  |                         |   | 3 | 4 | 5 |   |   |   |         | nuclear       |        |        |        | x      |            |   | <ul style="list-style-type: none"> <li>• [HRA Washington, 2001]</li> <li>• [Straeter, 2001]</li> </ul>  |
| 299. | FACET (Future ATM (Air Traffic Management) Concepts Evaluation Tool) | FTS    | OpR     | 2000 or older | FACET is an air traffic management (ATM) modelling and simulation capability. Its purpose is to provide an environment for the development and evaluation of advanced ATM concepts. FACET can model system-wide airspace operations over the entire US. It uses flight plan data to determine aircraft routing. As options, the routes can be automatically modified to direct routes or windoptimal routes. FACET then uses aircraft performance characteristics, winds aloft, and kinematic equations to compute flight trajectories. It then computes sector loading and airspace complexity. As an option, FACET can compute and simulate advanced concepts such as: aircraft self-separation and National Playbook rerouting. FACET also models the en-route impact of ground delay programs and miles-in-trail restrictions. | Developed at NASA Ames Research Center. FACET is capable of operating in one of the following four modes: Simulation, Playback, Hybrid, and Live.  |                         |   | 2 |   |   | 5 |   |   |         | ATM, aviation |        |        |        |        | x          |   | <ul style="list-style-type: none"> <li>• [GAIN ATM, 2003]</li> <li>• [Bilimoria00]</li> <li>• [FACET User manual, 2006]</li> <li>• [Sridhar et al, 2002]</li> </ul> |

| 300. | Factor Analysis               | Math   | Mod ?     | 1900          | The purpose of factor analysis is to discover simple patterns in the pattern of relationships among the variables. In particular, it seeks to discover if the observed variables can be explained largely or entirely in terms of a much smaller number of variables called factors. Statistical method.  | Factor analysis was invented 100 years ago by psychologist Charles Spearman, who hypothesized that the enormous variety of tests of mental ability--measures of mathematical skill, vocabulary, other verbal skills, artistic skills, logical reasoning ability, etc.--could all be explained by one underlying "factor" of general intelligence. Method is used in fields that deal with large quantities of data. |                         |   |   |   |   | 5 |   |   |         |             |        | social, manufacturing, healthcare  | x      |        |            |  |  |  | <ul style="list-style-type: none"> <li>• [Darlington]</li> <li>• [Rakowsky]</li> </ul>                               |
| 301. | Fail safety                   | Gen    | Des       | 1987 or older | A fail-safe design is a design that enables a system to continue operation, possibly at a reduced level (also known as graceful degradation), rather than failing completely, when some part of the system fails. That is, the system as a whole is not stopped due to problems either in the hardware or the software. Aim is to design a system such that failures will drive the system to a safe state.   | Useful for systems where there are safe plant states. Also referred to as fault tolerance. See also Memorizing Executed Cases. See also Vital Coded Processor.  |                         |   |   |   |   |   | 6 |   |         |             |        | aircraft, manufacturing, rail, space, electronics, avionics, road, nuclear | x      | x      |            |  |  |  | <ul style="list-style-type: none"> <li>• [Bishop, 1990]</li> </ul>   |
| 302. | Failure Assertion Programming | Step   | SwD       | 1995 or older | Detects residual software design faults during execution of a program, in order to prevent safety critical failures of the system and to continue operation for high reliability. Follows the idea of checking a pre-condition (before a sequence of statements is executed, the initial conditions are checked for validity) and a post-condition (results are checked after the execution of a sequence of statements). If either the pre-condition or the post-condition is not fulfilled, the processing reports the error. | Software architecture phase. Similar to Defensive programming. See also Software Testing.   |                         |   |   |   |   |   |   | 7 |         |             |        | software   |        | x      |            |  |  |  | <ul style="list-style-type: none"> <li>• [EN 50128, 1996]</li> <li>• [Heisel, 2007]</li> <li>• [Rakowsky]</li> </ul> |
| 303. | Failure Tracking              | Dat    | HwD , Dat | 1983 or older | Failure tracking is used to compile and store data upon which benchmarking can be performed. Failure tracking ensures the collection of quality data that reflects the system as a whole. Aim is to minimise the consequences of detected failures in the hardware and software.  | Desirable for safety-related applications. Tools available. See also HTRR and SRMTS.  |                         |   |   |   |   |   | 6 |   |         |             |        | electronics  | x      | x      |            |  |  |  | <ul style="list-style-type: none"> <li>• [Bishop, 1990]</li> </ul>   |

| 304. | Fallible machine Human Error                                | Gen    | HRA     | 1990 | A model of human information processing that accounts for a variety of empirical findings. The important feature of the model is that items in a long term "Knowledge base" (such as task knowledge) are "activated" and recalled into working memory by processes that depend in the current contents of the working memory and sensory inputs. Items that are recalled will ultimately be used in making decisions that result in motor outputs. Central to the operation of this 'machine' are the processes by which long term memory items are 'activated' in a way that allows them to be selected for use. According to the model, two processes govern the activation of long term memory items: <i>similarity matching</i> and <i>frequency gambling</i> . Briefly stated, similarity matching means that items are activated on the basis of how closely they match environmental and task dependent cues, and frequency gambling means that items receive greater activation if they have been activated more frequently in the past. | The concept of fallible machine was proposed by James Reason (1990).   |                         |   | 3 |   |   |   |   |   |         |                         |        | no-domain-found |        |        | x          |   |  | <ul style="list-style-type: none"> <li>[Fields, 2001]</li> <li>[Reason, 1990]</li> </ul> |
| 305. | FANOMOS (Flight track and Aircraft Noise Monitoring System) | Min    | Dat     | 1982 | FANOMOS aims to monitor and control the impact of aircraft noise on built-up areas around airports. It has the following main functions: Flight track reconstruction, Monitoring violation of prescribed flight routes, Correlation between noise measurements and flights, Correlation between complaint data and flights, Calculation and monitoring of actual noise exposure, Statistical processing of flight data. FANOMOS is also used to collect statistical data of aircraft trajectories for safety studies. It includes a database of aircraft trajectories in the Netherlands since 2001.   | Developed by NLR. Experience with FANOMOS includes the monitoring of flight tracks and/or noise in the vicinity of Amsterdam Airport Schiphol, Rotterdam Airport, Maastricht/Aachen Airport, Manchester, Zürich and all major airports in Germany (this is referred to as STANLY_Track). FANOMOS software has been made available for integration in the Global Environment System (GEMS) offered by Lochard Pty., Melbourne, Australia. Lochard GEMS systems, including FANOMOS software, are installed world-wide at over 25 airports. |                         |   |   |   |   |   | 7 |   |         | <a href="#">airport</a> |        |                 |        | x      |            | <ul style="list-style-type: none"> <li>[FANOMOS]</li> <li>[KleinObbink &amp; Smit, 2004]</li> </ul> |  |  |

| 306. | FAST<br>(Functional Analysis System Technique)      | Stat   | Mod,<br>Task | 1965                | Visually displays the interrelationships between all functions that must be performed to achieve the basic function. The goal is to provide an understanding of how the system works and how cost-effective modifications can be incorporated. Steps are: 1 Define all of the functions using the verb-noun pairs. Write these noun-verb pairs on cards or sticky notes so that they can be easily manipulated; 2 Select the two-word pairs that best describe the basic function; 3 Use the basic function to create a branching tree structure from the cards described in 2 above; 4 Verify the logic structure; 5 Delineate the limits of responsibility of the study so that the analysis does not go on to functions outside of the scope.  | FAST was first introduced in 1965 by the Society of American Value Engineers. This tool is used in the early stages of design to investigate system functions in a hierarchical format and to analyse and structure problems (e.g., in allocation of function). It asks 'how' a sub-task links to tasks higher up the task hierarchy, and 'why' the super-ordinate tasks are dependent on the sub-tasks.   |                         | 2 |   |   |   |   |   |   |         |             |        |        |        |        |            |  | <ul style="list-style-type: none"> <li>• [HIFA Data]</li> <li>• [Kirwan &amp; Ainsworth, 1992]</li> <li>• [FAA HFW]</li> <li>• [Sharit, 1997]</li> <li>• [DeMarle, 1992]</li> <li>• [Roussot, 2003]</li> </ul> |   |
| 307. | FAST Method<br>(Future Aviation Safety Team Method) | Step   | Hzi          | 2005<br>and<br>2010 | The FAST Method is aimed at identifying future hazards due to future changes within the aviation system. Ten steps: 1: Define suites of proposed changes, anticipated timeframe for deployment, and their associated developer communities; 2: Define enablers required to implement changes; 3: Identify elements of the FAST description of the future state of aviation relevant to the set of system-wide changes and domain-specific "interactions"; 4: Collect hazards and degradation/failure scenarios previously identified by developers of proposed concepts of operation (if available); 5: Identify new, emergent hazards by contrasting the results of step 4 against the results of step 3; 6: Group hazards into themes and architectures; 7: Formulate novel system-wide failure scenarios by conducting interaction analysis among emergent hazards and existing hazards and by examining the hazard themes and architectures; 8: Identify watch items for the detection of system-wide emergent hazards, specific vulnerabilities or possible failure scenarios; 9: Perform hazard analysis and risk assessment considering existing and planned mitigations according to best practices and existing organizational procedures; 10: Record concerns/ recommendations and disseminate results. | The first version of the FAST method was published in 2005. The 2010 version (presented in the previous column) was developed at the behest of the CAST/JIMDAT following re-activation of the Future Aviation Safety Team in 2009, and incorporates an update of all steps. One key element of the FAST Method is a list of AoC (Areas of Change), which are generic descriptions of the major changes affecting the aviation system in the years to come. This list is regularly updated. | 1                       | 2 | 3 | 4 |   |   |   |   |         |             |        |        |        |        |            |  |  | <ul style="list-style-type: none"> <li>• [FAST method, 2005]</li> </ul> |
|      | Fast-Time Simulation                                |        |              |                     |   | See Computer modelling and simulation  |                         |   |   |   |   |   |   |   |         |             |        |        |        |        |            |  |  |   |
| 308. | Fault Injection                                     | Step   | SwD          | 1970<br>s           | Faults are injected into the code to see how the software reacts. When executed, a fault may cause an error, which is an invalid state within a system boundary. An error may cause further errors within the system boundary, therefore each new error acts as a fault, or it may propagate to the system boundary and be observable.  | See also Software Testing.   |                         |   |   |   |   |   |   |   |         |             |        |        |        |        |            |  | <ul style="list-style-type: none"> <li>• [FaultInjection]</li> <li>• [Voas, 1997a]</li> <li>• [Voas, 1997b]</li> </ul>   |   |

| 313. | FEA<br>(Front-End Analysis)       | Int    | Trai    | 1993 | Comprises four analyses: (1) Performance analysis: Determine if it is a training/ incentive/ organisational problem. I.e., identify who has the performance problem (management/ workers, faculty/learners), the cause of the problem, and appropriate solutions. (2) Environmental analysis: Accommodate organisational climate, physical factors, and socio-cultural climate to determine how these factors affect the problem. (3) Learner analysis: Identify learner/ trainee/ employee characteristics and individual differences that may impact on learning / performance, such as prior knowledge, personality variables, aptitude variables, and cognitive styles. (4) Needs assessment: Determine if an instructional need exists by using some combination of methods and techniques. | Also referred to as Training Systems Requirements Analysis.   |                         |   |   | 3 |   | 5 |   |   |         |   |                  | social |        |        | x          | x  | x   | <ul style="list-style-type: none"> <li>• [FEA web]</li> <li>• [IDKB]</li> </ul> |
| 314. | FEMo<br>(Functional Energy Model) | Stat   | Mod     | 2001 | Model that can be used to study the circulation of energy flows in a technical system, localise the links with the operators and thus identify potentially hazardous phenomena. The model consists of 4 elements: a) frontiers that delimit a component in relation to its external environment; b) functional surfaces that designate the interfaces between a component and its environment. c) links that associate two functional surfaces that do not belong to the same component. d) internal links that associate two functional surfaces belonging to the same component.   | Elements c) and d) can be classed into three types: conductive (C), semi-conductive (SC) or insulating (I). See also Barrier Analysis, and see ETBA.  |                         | 2 | 3 |   |   |   |   |   |         |   | (manufacturing ) | x      |        |        |            |  | <ul style="list-style-type: none"> <li>• [DeGalvez et al., 2016]</li> </ul> |   |
| 315. | FFC<br>(Future Flight Central)    | RTS    | Des     | 1999 | Full-scale high fidelity interactive Air Traffic Control Tower simulator that aims to use human-in-the-loop simulation to study improvements to airport safety and capacity. It is designed to allow virtual reality tests of new tower procedures, airport designs and technologies.  | Opened December 13, 1999 at NASA Ames Research Center, Moffett Field, California. Its design and development was a joint NASA and FAA supported project. NASA maintains and operates the simulator. |                         |   | 3 |   |   |   | 7 |   |         | ATM, airport                                      |                  |        | x      | x      |            | <ul style="list-style-type: none"> <li>• [FFC guide 2004]</li> <li>• [FFC web]</li> <li>• [GAIN ATM, 2003]</li> <li>• [SAP15]</li> </ul>   |   |   |
| 316. | FFD<br>(Functional Flow Diagram)  | Stat   | Mod     | 1955 | Block diagram that illustrates the relationship between different functions. It is constructed by identifying the functions to be performed in the system, and then arranging these as a sequence of rectangular blocks, which represent the interrelationships between the functions. AND and OR gates are used to represent necessary sequences of functions or alternative courses of action.   | Is called the most popular systems method for the determination of functional requirements. FFDs are sometimes called Function Flow Block Diagrams. Tool: FAST                                      |                         | 2 |   |   |   |   |   |   |         | defence, space, chemical, nuclear, road, aviation | x                |        |        |        |            | <ul style="list-style-type: none"> <li>• [HEAT overview]</li> <li>• [Kirwan &amp; Ainsworth, 1992]</li> <li>• [MIL-HDBK, 1999]</li> <li>• [FAA HFW]</li> <li>• [Beevis, 1992]</li> </ul> |   |   |

| 317. | FHA<br>(Functional Hazard Assessment)<br>according to JAR-25   | Step   | HZA     | 1992<br>or<br>older | In FHA according to JAR-25, all system functions are systematically examined in order to identify potential failure conditions which the system can cause or contribute to; not only if it malfunctions, but also in its normal response to unusual or abnormal external factors. Each failure condition is classified according to its severity. If the system is not complex and similar to systems used on other aeroplanes, this identification and classification may be derived from design and installation appraisals and the service experience of the comparable, previously-approved, systems. If the system is complex it is necessary to systematically postulate the effects on the safety of the aeroplane and its occupants resulting from any possible failure, considered both individually and in combination with other failures or events.   | FHA was developed by the aerospace industry to bridge between hardware and software, since functions are generally identified without specific implementations. |                         |   | 3 |   |   |   |   |   |         |             |        | aircraft              | x      |        |            |  |  | <ul style="list-style-type: none"> <li>• [JAR 25.1309]</li> <li>• [Klompstra &amp; Everdij, 1997]</li> <li>• [Mauri, 2000]</li> <li>• [MUFTIS3.2-I, 1996]</li> </ul>                 |
| 318. | FHA<br>(Functional Hazard Assessment)<br>according to ARP 4761 | Step   | HZA     | 1994                | FHA according to ARP 4761 examines aircraft and system functions to identify potential functional failures and classifies the hazards associated with specific failure conditions. The FHA is developed early in the development process and is updated as new functions or failure conditions are identified. FHA is applied at two different levels: an aircraft level and a system level. The former is a qualitative assessment of the basic known aircraft functions, the latter examines each system which integrates multiple aircraft functions. An aircraft level FHA, which is a high level FHA, is applied during an activity to determine functional failure consequences and applications; i.e. to determine the classification of the failure conditions associated with each function. This classification is based on hazard severity. A system level FHA is applied during an activity in which functions are allocated to systems and people; this stage consists of establishing the appropriate grouping of aircraft functions and the allocation of the related requirements to people or systems. The allocation should define inputs, processes performed and outputs. From the function allocations and the associated failure consequences, further specific system requirements necessary to achieve the safety objectives are determined. The output is a set of requirements for each human activity and aircraft system together with associated interfaces. | This FHA is a refinement and extension of the FHA according to JAR-25. It covers software as well as hardware.  |                         |   | 3 |   |   |   |   |   |         |             |        | aircraft,<br>avionics | x      | x      |            |  |  | <ul style="list-style-type: none"> <li>• [ARP 4754]</li> <li>• [ARP 4761]</li> <li>• [Klompstra &amp; Everdij, 1997]</li> <li>• [Lawrence, 1999]</li> <li>• [Mauri, 2000]</li> </ul> |

| 319. | FHA (Functional Hazard Assessment) according to EATMP SAM | Step   | HzA     | 2000          | The FHA according to EATMP SAM analyses the potential consequences on safety resulting from the loss or degradation of system functions. Using service experience, engineering and operational judgement, the severity of each hazard effect is determined qualitatively and is placed in a class 1, 2, 3, 4 or 5 (with class 1 referring the most severe effect, and class 5 referring to no effect). Safety Objectives determine the maximum tolerable probability of occurrence of a hazard, in order to achieve a tolerable risk level. Five substeps are identified: 1) FHA initiation; 2) FHA planning; 3) Safety objectives specification; 4a) FHA validation; 4b) FHA verification; 4c) FHA assurance process; 5) FHA completion. Most of these steps consist of substeps. | The FHA according to EATMP SAM is a refinement and extension of the FHA according to JAR-25 and of the FHA according to ARP 4761, but its scope is extended to Air Navigation Systems, covering AIS (Aeronautical Information Services), SAR (Search and Rescue) and ATM (Air Traffic Management).  | 1                       |   | 3 | 4 |   |   |   |   |         |  |         | ATM    | x      |        |            |  |   |  | <ul style="list-style-type: none"> <li>• [EHQ-SAM, 2002]</li> <li>• [Review of SAM techniques, 2004]</li> </ul> |
| 320. | FHA or FaHA (Fault Hazard Analysis)                       | Tab    | HzA     | 1965          | A system safety technique that is an offshoot from FMEA. It is similar to FMEA however failures that could present hazards are evaluated rather than hazards themselves. A typical FHA form contains the following columns: 1) Component identification; 2) Failure probability; 3) Failure modes; 4) Percent failures by mode; 5) Effect of failure (traced up to some relevant interface); 6) Identification of upstream component that could command or initiate the fault; 7) Factors that could cause secondary failures; 8) Remarks. The FHA is generally like an FMEA or FMECA with the addition of the extra information in columns 6 and 7.   | Developed by Boeing for the Minuteman program. FHA was developed as a special purpose tool for use on projects involving many organisations. It is valuable for detecting faults that cross organisational interfaces. Any electrical, electronics, avionics, or hardware system, sub-system can be analysed to identify failures, malfunctions, anomalies, and faults, that can result in hazards. Hazard analysis during system definition and development phase. Emphasis on the cause. Inductive. FHA is very similar to PHA and is a subset of FMEA. Weakness is that it does not discover hazards caused by multiple faults. It also tends to overlook hazards that do not result entirely from failure modes, such as poor design, timing errors, etc. |                         |   | 3 |   |   |   |   |   |         |  | defence | x      |        |        |            |  |   | <ul style="list-style-type: none"> <li>• [FAA00]</li> <li>• [FT handbook, 1981]</li> <li>• [FT handbook, 2002]</li> <li>• [Leveson, 1995]</li> <li>• [ΣΣ93, ΣΣ97]</li> <li>• [GAIN AFSA, 2003]</li> <li>• [Ericson, 2005]</li> </ul> |   |

| 329. | Flow Analysis  | Stat   | Hzi     | 1973 or older | The analysis evaluates confined or unconfined flow of fluids or energy, intentional or unintentional, from one component/sub-system/ system to another. In software engineering, the term refers to a method used to detect poor and potentially incorrect software program structures. In the latter case, there are two versions: Data FA and Control FA. Data FA derives information about the dynamic behaviour of a program by only examining the static code, thus collecting information about the way the variables are used. Control FA is a static code analysis technique for determining the control flow of a program; the control flow is expressed as a control flow graph. | The technique is applicable to all systems which transport or which control the flow of fluids or energy. Complementary to inspection methods. Useful especially if there is suitable tool support. Tools available.  |                         |   | 3 |   |   |   |   |   | chemical, food, environment, nuclear, electronics   | x           | x      |        |        |        |            |  | • [Bishop, 1990]<br>• [FAA00]<br>• [ΣΣ93, ΣΣ97] |

| 331. | FMECA<br>(Failure Mode Effect and Criticality Analysis) | Tab    | HzA     | 1949          | Is FMEA completed with a measure for criticality (i.e. probability of occurrence and gravity of consequences) of each failure mode. Aim is to rank the criticality of components that could result in injury, damage or system degradation through single-point failures in order to identify those components that might need special attention and control measures during design or operation.  | Useful for safety critical hardware systems where reliability data of the components is available. See also Criticality Analysis.                                       |                         |   |   | 3 |   | 5 |   |   |         |             |        |        |        |        |            |  | <ul style="list-style-type: none"> <li>[Bishop, 1990]</li> <li>[FAA00]</li> <li>[Leveson, 1995]</li> <li>[MUFTIS3.2-I, 1996]</li> <li>[ΣΣ93, ΣΣ97]</li> <li>[Pentti &amp; Atte, 2002]</li> <li>[DNV-HSE, 2001]</li> <li>[Hoegen, 1997]</li> <li>[Kumamoto &amp; Henley, 1996]</li> <li>[Matra-HSIA, 1999]</li> <li>[Page et al, 1992]</li> <li>[Parker et al, 1991],</li> <li>[Rademakers et al, 1992]</li> <li>[Richardson, 1992]</li> <li>[Amberkar et al, 2001]</li> <li>[Storey, 1996]</li> <li>[Villemeur, 1991]</li> <li>[GAIN AFSA, 2003]</li> </ul> |
| 332. | FMES<br>(Failure Modes and Effects Summary)             | Tab    | HZA     | 1994 or older | Groups failure modes with like effects. FMES failure rate is sum of failure rates coming from each FMEA. Is used as an aid to quantify primary FTA events.   | Is used as an interface between FMEA/FMECA and FTA.   |                         |   |   |   |   | 5 |   |   |         |             |        |        |        |        |            |  | <ul style="list-style-type: none"> <li>[ARP 4761]</li> </ul>  |
| 333. | FOQA<br>(Flight Operations Quality Assurance)           | Dat    | Dat     | 1995          | The objective of the FOQA database is to identify and correct safety deficiencies in flight operations using information about trends and safety risks. This information can be used to identify trends in the aviation system. The air carriers own the FOQA data and use the data to identify possible safety trends or problems.  | Currently, 13 air carriers participate in FOQA by equipping aircraft with data collection devices that monitor the aircraft engines, flight paths, and other variables. |                         |   |   |   |   |   |   |   | 8       |             |        |        |        |        |            |  | <ul style="list-style-type: none"> <li>[Hansen et al., 2006]</li> </ul>   |
| 334. | FORAS<br>(Flight Operations Risk Assessment System )    | Math   | OpR     | 2004          | FORAS gives a quantitative assessment of accident / incident risk for a flight operation, broken down into a variety of subgroups: by fleet, region, route, or individual flight. This assessment is performed using a mathematical model which synthesizes a variety of inputs, including information on crew, weather, management policy and procedures, airports, traffic flow, aircraft, and dispatch operations. The system aims to identify those elements that contribute most significantly to the calculated risk, and in some cases to suggest possible interventions. |   |                         |   |   |   |   | 5 | 6 |   |         |             |        |        |        |        |            |  | <ul style="list-style-type: none"> <li>[NRLMMD, 2006]</li> <li>[Cranfield, 2005]</li> </ul>   |
| 335. | Formal Inspections                                      | Tab    | Val     | 1996 or older | A safety checklist, based on safety requirements, is created to follow when reviewing the requirements. After inspection, the safety representative reviews the official findings of the inspection and translates any that require safety follow-up on to a worksheet.  |   |                         |   |   |   |   |   |   |   | 7       |             |        |        |        |        |            |  | <ul style="list-style-type: none"> <li>[NASA-GB-1740.13-96]</li> </ul>  |

| 336. | Formal Methods   | Math   | Val     |               | Formal Methods refer to techniques and tools based on mathematical modelling and formal logic that are used to specify and verify requirements and designs for computer systems and software.   | Generation of code is the ultimate output of formal methods. In a pure formal methods system, analysis of code is not required. In practice, however, attempts are often made to apply formal methods to existing code after the fact.  |                         |   |   |   | 4 |   | 6 |   |         | electronics, security, aircraft, rail, avionics, space, nuclear |        | x      |        |        |            |   | <ul style="list-style-type: none"> <li>• [DO-178B, 1992]</li> <li>• [EN 50128, 1996]</li> <li>• [FAA00]</li> <li>• [NASA-GB-1740.13-96]</li> <li>• [Rakowsky]</li> <li>• [Storey, 1996]</li> </ul> |
| 337. | Formal Proof   | Step   | Val     | 1969 or older | A number of assertions are stated at various locations in the program and they are used as pre and post conditions to various paths in the program. The proof consists of showing that the program transfers the preconditions into the post conditions according to a set of logical rules and that the program terminates.  | Software verification and testing phase.  |                         |   |   |   |   |   | 6 |   |         | software  |        | x      |        |        |            |   | <ul style="list-style-type: none"> <li>• [EN 50128, 1996]</li> <li>• [Rakowsky]</li> </ul>   |
| 338. | Formally Designed Hardware or Formal Design (Hardware) | Gen    | Des     | 1988 or older | Aim of formally designed hardware is to prove that the hardware design meets its specification. A formal specification is a mathematical description of the hardware that may be used to develop an implementation. It describes what the system should do, not (necessarily) how the system should do it. Provably correct refinement steps can be used to transform a specification into a design, and ultimately into an actual implementation, that is correct by construction. | Best applied in context where all components are formally proven. Can be used in combination with N out of M voting. Tools available. See also Formal Methods.  |                         |   |   |   |   |   | 6 |   |         | electronics, road, aircraft                                     | x      |        |        |        |            |   | <ul style="list-style-type: none"> <li>• [Bishop, 1990]</li> </ul>   |
| 339. | Forward Recovery                                       | Stat   | Mit     | 1989 or older | The aim of forward recovery is to apply corrections to a damaged state in a 'bottom-up' fashion. This starts at the lowest levels, up to a failure within the broader system. For this approach to work, some understanding of errors that have occurred is needed. If errors are very well understood, the Forward Recovery approach can give rise to efficient and effective solutions.   | Software architecture phase. See also Backward Recovery.  |                         |   |   |   |   |   | 6 |   |         | software  |        | x      |        |        |            |   | <ul style="list-style-type: none"> <li>• [EN 50128, 1996]</li> <li>• [Rakowsky]</li> <li>• [SSCS]</li> </ul>   |
| 340. | FOSA (Flight Operational Safety Assessment)            | Step   | OpR     | 2009          | FOSA is a safety assessment methodology aimed at operations considering aircraft on approach to an airport, for which they require authorization related to their navigation performance. FOSA combines quantitative and qualitative analyses and evaluations of the navigation systems, aircraft systems, operational procedures, hazards, failure mitigations, normal, rare-normal and non-normal conditions, and the operational environment.                                    |   | 1                       | 2 | 3 | 4 | 5 | 6 | 7 |   |         | aviation  |        |        |        |        | x          |   | <ul style="list-style-type: none"> <li>• [Smith, 2010]</li> </ul>  |
| 341. | FPC (Flow Process Chart)                               | Stat   | Task    | 1921          | A Flow Process Chart is a graph with arrows and six types of nodes: Operation, Move, Delay, Store, Inspect process, and Decision. It allows a closer examination of the overall process charts for material and/or worker flow and includes transportation, storage and delays.   | Developed by American Society of Mechanical Engineers (ASME). Used for physical processes. Similarities with Operations Analysis in [FAA00]. FPC were a precursor to Operational Sequence Diagram (OSD). See also PFD (Process Flow Diagram), which is used for chemical processes. |                         |   | 2 |   |   |   |   |   |         | manufacturing, management, defence, navy, nuclear               | x      |        |        |        | x          | x | <ul style="list-style-type: none"> <li>• [FAA00]</li> <li>• [HEAT overview]</li> <li>• [MIL-HDBK, 1999]</li> <li>• [Kirwan &amp; Ainsworth, 1992]</li> <li>• [Beevis, 1992]</li> </ul>             |

| 342. | FPTN<br>(Failure Propagation and Transformation Notation) | Stat   | HzA      | 1993 | Hierarchical graphical notation that represents system failure behaviour. Is linked to design notation and is both an inductive and deductive analysis. FPTN makes consistency checks and is designed to be used at all stages of the life cycle. FPTN represents a system as a set of interconnected modules; these might represent anything from a complete system to a few lines of program code. The connections between these modules are failure modes, which propagate between them.  | Developed by Fenelon & McDerimid. Originated from HAZOP  |                         |   |   |   | 4 |   |   |   |         |             |        | manufacturing  |        | x      |            |   |  |  | • [Mauri, 2000]  |
| 343. | FRAM<br>(Functional Resonance Accident Method)            | Stat   | Mod, Ret | 2004 | FRAM is a qualitative accident model that describes how functions of (sub)systems may under unfavourable conditions resonate and create situations that are running out of control (incidents / accidents). It can be used in the search for function (process) variations and conditions that influence each other and then may resonate in the case of risk analysis, or have resonated in the case of accident analysis. The model syntax consists of multiple hexagons that are coupled. Each hexagon represents an activity or function. The corners of each hexagon are labelled (T): Time available; This can be a constraint but can also be considered as a special kind of resource; (C): Control, i.e. that which supervises or adjusts a function. Can be plans, procedures, guidelines or other functions; (O): Output, i.e. that which is produced by function. Constitute links to subsequent functions; (R): Resource, i.e. that which is needed or consumed by function to process input (e.g., matter, energy, hardware, software, manpower); (P): Precondition, i.e. system conditions that must be fulfilled before a function can be carried out; and (I): Input, i.e. that which is used or transformed to produce the output. Constitutes the link to previous functions. | Developed by Erik Hollnagel. FRAM is based on the premise that performance variability, internal variability and external variability are normal, in the sense that performance is never stable in a complex system as aviation. Performance variability is required to be sufficiently flexible in a complex environment and it is desired to allow learning from high and low performance events. FRAM means 'forward' in Norwegian and Swedish. |                         |   |   |   | 4 |   |   |   |         |             |        | aviation, ATM, healthcare, nuclear, aircraft, maritime |        |        | x          | x |  |  | • [Hollnagel & Goteman, 2004]<br>• [Hollnagel, 2004]<br>• [Hollnagel, 2006]  |
| 344. | FSAS<br>(Facility Safety Assessment System)               | Dat    | Dat      | 2005 | FSAS is a database and web-based tool that contains information related to the safety assessment process of a facility. This information includes evaluation checklists, reports, facility information, tracking information, and response data, including mitigation plans. FSAS is used for air traffic facilities conducting internal evaluations and for conducting audits. It is a central collection point for both the evaluation and the audit data as it is completed. It provides a means for internal facility communication on the status of the evaluation and on identified areas not meeting requirements yet.  | Maintained by FAA ATO Safety for U.S.A. In fiscal year (FY) 2005, the first use of FSAS occurred and in FY 2006 all ATC facilities became responsible for performing facility self-assessments.  | 1                       |   |   |   |   |   |   |   |         | 7           |        | ATM  | x      |        |            |   |  |  | • [ATO SMS Manual v3.0]<br>• [Notice JO 7010.21]<br>• [FSAS User Guide 2005] |

| 345. | FSM<br>(Finite State Machines)            | Stat   | Mod     | 1955                | An FSM is a behaviour model composed of a finite number of states, transitions between those states, and actions, similar to a flow graph in which one can inspect the way logic runs when certain conditions are met. Aim is to model and analyse the control structure of a purely discrete state system.   | A simple yet powerful technique for event driven systems. Two variants are a Mealy machine (1955), which is an FSM that generates an output based on its current state and input, and a Moore machine (1956), which is an FSM where the outputs are determined by the current state alone and do not depend directly on the input. Tools available. Similar to State Transition Diagrams. Sometimes referred to as (Finite State) Automaton.   |                         |   |   | 4 |   |   |   |   |         |             | electronics, environment, social, defence, navy, ATM, healthcare, software | x      | x      |        |            |   | <ul style="list-style-type: none"> <li>• [Bishop, 1990]</li> <li>• [EN 50128, 1996]</li> <li>• [HEAT overview]</li> <li>• [Rakowsky]</li> <li>• [Beevis, 1992]</li> </ul> |
| 346. | FSMA<br>(Fault-Symptom Matrix Analysis)   | Tab    | HZA     | 1981                | A Fault-Symptom Matrix is a matrix with vertically the faults of a system and horizontally the possible symptoms. The cells contain probabilities of occurrence.  | Linked to Confusion Matrix Approach.   |                         |   | 3 | 5 |   |   |   |   |         |             | nuclear  | x      |        |        |            | <ul style="list-style-type: none"> <li>• [Kirwan, 1994]</li> <li>• [Qiu&amp;al]</li> </ul>  |   |
| 347. | FSSA<br>(Facility System Safety Analysis) | Tab    | HZA     | 1992<br>or<br>older | A Facility Systems Safety Analysis (FSSA) is a systematic approach toward: Identifying credible hazards associated with the operation of a facility; Defining the hazards in terms of severity and probability; Assessing the controls for those hazards; Making recommendations toward reduction of the severity and/or probability of occurrence; and Identifying documentation to place under configuration control. A FSSA is performed on new facilities, or on existing facilities that have undergone a construction modification. Aim is to document the safety bases for and commitments to the control of subsequent operations. This includes staffing and qualification of operating crews; the development, testing, validation, and inservice refinement of procedures and personnel training materials; and the safety analysis of the person-machine interface for operations and maintenance. Considerations of reliable operations, surveillance, and maintenance and the associated human factors safety analysis are developed in parallel and integrated with hardware safety design and analysis. | Facilities are analysed to identify hazards and potential accidents associated with the facility and systems, components, equipment, or structures. The results of the FSSA are documented in a SAR (Safety Analysis report). Standard Operating Procedures (SOP's) and Checklists, Configuration Control Documentation (CCD), and Other special items identified by the Facility Team ensure that hazard controls (e.g., procedures, interlocks, etc.) have been documented and placed under configuration control. |                         |   | 3 |   | 6 |   |   |   |         |             | space, aircraft, (nuclear), (chemical)                                     | x      |        | x      | x          | <ul style="list-style-type: none"> <li>• [FAA AC431]</li> <li>• [FAA00]</li> <li>• [ΣΣ93, ΣΣ97]</li> <li>• [NASA, 2006-FSSA]</li> </ul> |   |

| 348. | FTA<br>(Fault Tree Analysis)  | Stat   | HZA,<br>Mod | 1961                | The objectives of FTA are to determine how a higher-level failure may be caused by lower-level failures, and to quantify the probability of occurrence of such higher-level failure. The analyst starts from a top-level undesired event, which becomes the top of the Fault Tree. Next, the analyst determines all credible single faults and combinations of failures at the next lower level of design that could cause this top event, and interconnects them with appropriate symbols to extend each fault event to the next lower level. The symbols predominantly used are for AND and OR relations, but other symbols are available (e.g., 'exclusive or', 'priority and', 'external event'). The analysis proceeds down through successively more detailed (lower) levels of design, until either the top-level requirement can be satisfied, or an event is uncovered that is not further developed. A common approach to analyze a fault tree is to determine its minimal cut sets, i.e. minimal sets of primary failures, such that if all these simultaneously exist, the top event exists. Quantification of the fault tree is usually done through quantification of its minimal cut sets. | Former name is CTM (Cause Tree Method). Developed in 1961 by Bell Telephone Laboratories for US ICBM (Intercontinental Ballistic Missile system) program; guide published in 1981. Tools are available, e.g. Fault Tree+, FaultREASE, RISKMAN. The logical operations are covered within IEC (International Electrotechnical Commission) 1025 international standard. FTA is intended to be used for analysis of complex technical systems, primarily hardware systems. Applications to software failures and to human error exist, but for these, quantification is much more challenging regarding the Analysis part of FTA. See also CBFTA, CCDM or CCA, DD, DTA, KTT, Logic Diagram, PRA, RBD, SFTA. |                         |   |   |   | 4 | 5 |   |   |         |             |        |        |        |        |            |  |  | <ul style="list-style-type: none"> <li>• [EN 50128, 1996]</li> <li>• [FAA00]</li> <li>• [FT Handbook, 2002]</li> <li>• [GAIN ATM, 2003]</li> <li>• [GAIN AFSA, 2003]</li> <li>• [Leveson, 1995]</li> <li>• [Mauri, 2000]</li> <li>• [MUFTIS3.2-I, 1996]</li> <li>• [ΣΣ93, ΣΣ97]</li> <li>• [Storey, 1996]</li> <li>• [Henley &amp; Kumamoto, 1992]</li> <li>• [DNV-HSE, 2001]</li> <li>• [Howat, 2002]</li> <li>• [Kumamoto &amp; Henley, 1996]</li> <li>• [Villemeur, 1991]</li> <li>• [Ericson, 1999]</li> </ul> |

| 349. | Function Allocation Trades  | Stat   | Mod         | 1986<br>or<br>older | Working in conjunction with project subsystem designers and using functional flows and other human error methods, plus past experience with similar systems, the practitioner makes a preliminary allocation of the actions, decisions, or functions shown in the previously used charts and diagrams to operators, equipment or software.  | Several techniques are proposed to work out the details in this method. Also referred to as Function Allocation Evaluation Matrix, or as Ad Hoc Function Allocation.   |                         | 2 |   | 4 |   |   |   |   |         |             |        |        | x      | x      | x          |  |  | <ul style="list-style-type: none"> <li>• [HEAT overview]</li> <li>• [MIL-HDBK, 1999]</li> <li>• [Beevis, 1992]</li> </ul>  |
| 350. | Functional Safety Assessment Method for Cooperative Automotive Architecture | Step   | Mit         | 2021                | The method aims to ensure that an automotive architecture is functionally safe to operate in given scenarios. The proposed method derives functional safety requirements (FSR) for a cooperative driving scenario and checks whether they are fulfilled in the technical software architecture of a vehicle. Cooperative driving refers to the collective optimization of the traffic participants' behaviour by sharing information using wireless communication.  | Functional safety in this context is defined as "an absence of unreasonable risk due to hazards caused by malfunctioning behaviour of electrical and/or electronic systems". Method follows ISO 26262 guidelines.  |                         | 2 | 3 |   |   | 6 |   |   |         |             |        |        |        | x      |            |  |  | <ul style="list-style-type: none"> <li>• [Kochanthara et al, 2021]</li> </ul>  |
| 351. | Fuzzy Logic   | Math   | Mod         | 1925                | Fuzzy logic is a superset of conventional (Boolean) logic that has been extended to handle the concept of partial truth: truth values between "completely true" and "completely false".   | The term fuzzy logic was introduced in 1965 by Dr. Lotfi Zadeh of University of California, but the approach has been studied since the 1920s. Software design & development phase.  |                         |   |   |   | 4 |   |   |   |         |             |        |        |        | x      |            |  |  | <ul style="list-style-type: none"> <li>• [EN 50128, 1996]</li> <li>• [FuzzyLogic]</li> <li>• [Rakowsky]</li> </ul>   |

| 352. | Gain Scheduling   | Math   | Mod     | 1968 about | Gain scheduling is an approach to control of non-linear systems that uses a family of linear controllers, each of which provides satisfactory control for a different operating point of the system. One or more observable variables, called the scheduling variables, are used to determine what operating region the system is currently in and to enable the appropriate linear controller. Aim is to achieve fault tolerance by storing pre-computed gain parameters. It requires an accurate FDD (Fault Detection and Diagnosis scheme) that monitors the status of the system.   | Popular methodology. See also FDD.   |                         |   |   |   |   |   |   | 6 |         |             |        |            | aviation, manufacturing, energy, nuclear, oil&gas, aircraft | x      |            |   |   |  |   | <ul style="list-style-type: none"> <li>• [Schram &amp; Verbruggen, 1998]</li> <li>• [Leith &amp; Leithead, 2000]</li> </ul> |
| 353. | Gantt Charts  | Stat   | Mod     | 1915       | Graphically illustrates time courses of functions and tasks. The functions and tasks may be used in flow-charting methods to address potential workload problems that may have implications for function allocation. May be applied to functions that are temporal (e.g., scheduling).  | Developed by Henry Laurence Gantt (1861-1919).   |                         |   | 2 |   |   |   |   |   |         |             |        | management |   |        | x          | x |   |  | <ul style="list-style-type: none"> <li>• [FAA HFW]</li> <li>• [Gantt, 2003]</li> </ul>  |   |
| 354. | Gas Model   | Math   | Col     | 1971       | Analytical accident risk model to determine probability of collision between aircraft or to assess air traffic controller workload. Based on the physical model of gas molecules in a heated chamber to estimate the number of conflicts between aircraft occupying some part of airspace. The model assumes that aircraft are uniformly and independently distributed within an area, i.e. a horizontal plane, or a volume. It is further assumed that aircraft travel in straight lines in directions which are independently and uniformly distributed between 0 and 360° and with speeds that are independent of the direction of travel and are drawn, independently for each aircraft, from a probability distribution. | This simple representation may be only suited to an uncontrolled part of airspace occupied by pleasure fliers who may indeed be flying in random directions. |                         |   |   |   |   |   | 5 |   |         |             |        | (ATM)      |   |        |            | x |   |  | <ul style="list-style-type: none"> <li>• [MUFTIS1.2, 1996]</li> <li>• [Alexander, 1970]</li> <li>• [Marks, 1963]</li> <li>• [Flanagan &amp; Willis, 1969]</li> <li>• [Graham &amp; Orr, 1969]</li> <li>• [Graham &amp; Orr, 1970]</li> <li>• [Endoh, 1982]</li> </ul> |   |

| 356. | GDTA<br>(Goal-Directed Task Analysis)       | Int    | Task    | 1993          | GDTA is a cognitive task analysis technique that is concerned with the situation awareness (SA) requirements necessary to complete a task. It focuses on the basic goals for each team role (which may change dynamically), the major decisions that should be made to accomplish these goals, and the SA requirements for each decision. GDTA attempts to determine what operators would ideally like to know to meet each goal. Structured interviews, observations of operators performing their tasks, as well as detailed analysis of documentation on users' tasks are used to complete the analysis process. GDTA aims to reveal information needs for complex decision making in environments such as air traffic control. | Developed by Mica R. Endsley.   |                         | 2 |   |   |   |   |   |   |         |             |        |        |        |        |            |  |  | <ul style="list-style-type: none"> <li>[FAA HFW]</li> <li>[Endsley, 1993]</li> <li>[Bolstad et al, 2002]</li> </ul> |
| 357. | GEMS<br>(Generic Error Modelling System)    | Tab    | HRA     | 1987          | GEMS is an error classification model that is designed to provide insight as to why an operator may move between skill-based or automatic rule based behaviour and rule or knowledge-based diagnosis. Errors are categorised as slips/lapses and mistakes. The result of GEMS is a taxonomy of error types that can be used to identify cognitive determinants in error sensitive environments. GEMS relies on the analyst either having insight to the tasks under scrutiny or the collaboration of a subject matter expert, and an appreciation of the psychological determinants of error.  | Proposed by James Reason. Based on variation of Step Ladder Model (SLM). Also referred to as extension of SRK (Skill, Rule, Knowledge). Rarely used as tool on its own.   |                         |   |   |   | 5 |   |   |   |         |             |        |        |        |        |            |  | <ul style="list-style-type: none"> <li>[Kirwan, 1994]</li> <li>[Kirwan, Part 1, 1998]</li> </ul>   |   |
| 358. | Generalised Gas Model                       | Math   | Col     | 1982 or older | Analytical model. Based on the gas model, but the aircraft do not always fly in random directions. Aim is to determine probability of collision between aircraft or to assess air traffic controller workload.   |   |                         |   |   |   | 5 |   |   |   |         |             |        |        |        |        |            |  | <ul style="list-style-type: none"> <li>[MUFTIS1.2, 1996]</li> <li>[Endoh, 1982]</li> <li>[Endoh &amp; Odoni, 1983]</li> </ul>                |   |
| 359. | Generalised Reich Collision Risk Model      | Math   | Col     | 1993          | The Generalized Reich collision risk model aims at evaluating collision risk between aircraft in an arbitrary network of lane segments incorporating hazards and human behavior. All types of aircraft collisions are considered, including airborne collisions and collisions between taxiing aircraft and aircraft landing or taking off. Since the model does not assume steady state distributions like the Reich model does, the pdfs for aircraft position and velocity may be time-dependent.   | To apply the Generalized Reich collision risk model, the pdfs have to be determined by means of Monte Carlo simulations of a stochastic dynamic model that includes pilot and controller behavior, technical and operational hazards, collision detection and avoidance maneuvers, weather influences, etc., including all interactions between these entities. See also TOPAZ. |                         |   |   |   | 5 |   |   |   |         |             |        |        |        |        |            |  | <ul style="list-style-type: none"> <li>[Bakker &amp; Blom, 1993]</li> <li>[Blom &amp; Bakker, 2002]</li> <li>[MUFTIS3.2-II, 1996]</li> </ul> |   |
| 360. | GFCM<br>(Gathered Fault Combination Method) | Stat   | HZA     | 1991 or older | Extension and generalisation of FMEA. A FMECA is made for all components of the system. Next, failure modes (or their combinations), which have the same effect are gathered in a tree.  | Qualitative and quantitative.   |                         |   | 3 | 4 | 5 |   |   |   |         |             |        |        |        |        |            |  |  | <ul style="list-style-type: none"> <li>[MUFTIS3.2-I, 1996]</li> <li>[Villemeur, 1991]</li> </ul>                    |
| 361. | GO Charts<br>(Graphics Oriented Charts)     | Stat   | HwD     | 1975          | A GO chart is graphical organizer to organise and summarise a text. | 365. | HACCP (Hazard Analysis and Critical Control Points)  | Step   | HZA, Mit | 1960 | HACCP aims at identifying, evaluating and controlling safety hazards in a food process, at the earliest possible point in the food chain. It is used to develop and maintain a system, which minimises the risk of contaminants. It identifies who is to be protected, from what, and how. Risks are identified and a corrective or preventative risk management option is selected and implemented to control the risk within the limits of acceptable risk standards. Steps are: 1. Identify hazards; 2. Determine the critical control points; 3. Determine the critical limits for each control point; 4. Monitor the critical limits; 5. Identify corrective action procedures (corrective action requests or CARs); 6. Establish records and control sheets; 7. Verify the HACCP plan | Developed by NASA in the 1960's to help prevent food poisoning in astronauts. A critical control point is defined as any point or procedure in a specific food system where loss of control may result in an unacceptable health risk. Whereas a control point is a point where loss of control may result in failure to meet (non-critical) quality specifications. Food safety risk can be divided into the following three categories: Microbiological Risks, Chemical Risks, and Physical Risks. |                         |   | 3 |   | 5 | 6 |   |   | food  |             |   |   |   | x | <ul style="list-style-type: none"> <li>[McGonicle]</li> </ul>   |  |

| 366. | Hatley notation                                   | Stat   | Des      | 1984          | The Hatley notation uses visual notations for modelling systems. Belongs to a class of graphical languages that may be called “embedded behaviour pattern” languages because it embeds a mechanism for describing patterns of behaviour within a flow diagram notation. Behaviour patterns describe different qualitative behaviours or modes, together with the events that cause changes in mode, for the entity being modelled. The flow notation models the movement of information through the system together with processes that use or change this information. Combining these two modelling capabilities makes it possible to model control of processes. A process may, for example, be turned on or off when a change in mode occurs. | Developed by Derek Hatley. A few years later it was extended to Hatley-Pirbhai notation with a complementary approach to high-level design.  |                         |   | 2 |   |   |   |   |   |           | aircraft, healthcare |        | x      |        |        |            |  |   | <ul style="list-style-type: none"> <li>• [Williams, 1991]</li> <li>• [Hatley &amp; Pirbhai, 1987]</li> </ul> |
| 367. | HAW (Hazard Analysis Worksheet)                   | Tab    | HzA      | 2003 or older | HAW is used to provide an initial overview of the hazards present in the overall flow of an operation. It is commonly presented as a table with column entries, e.g. Hazard ID; Hazard Description; Causes; System State; Existing Controls; Existing Control; Justification/ Supporting Data; Effects; Severity; Severity Rationale; Likelihood; Likelihood Rationale; Initial Risk; Safety Requirements; Organization Responsible for Implementing Safety Requirements; Predicted Residual Risk; Safety Performance Targets.  | The HAW is the non-acquisitions (i.e. operational phase) equivalent of the PHA. Can also be used to document hazards that were identified using other methods such as HACCP, SSHA. |                         |   |   | 3 |   | 5 | 6 |   | food, ATM | x                    |        | x      | x      |        |            |  | <ul style="list-style-type: none"> <li>• [ATO SMS Manual v3.0]</li> </ul> |  |

| 370. | Hazard Crystallisation               | Stat   | Mod     | 2006          | This technique aims to crystallise a long list of hazards into scenarios. Each scenario aims to bring into account all relevant ways in which a hazardous situation may develop and evolve, under influence of the related operational conditions, and the related hazards. The hazards may include those that create the hazardous situation (root hazards), as well as those that influence the safe resolution of the situation (resolution hazards).   | A hazard is defined as anything that may negatively influence safety. An example scenario is the evolution of a conflict between two aircraft. Examples of operational conditions are flight phase and location, number of traffic, environmental conditions.  |                         |   |   |   | 4 |   |   |   |         |             |   | ATM                    | x  | x  | x          | x | x   | <ul style="list-style-type: none"> <li>[Blom &amp; Stroeve &amp; DeJong, 2006]</li> <li>[Stroeve et al, 2009]</li> </ul>                  |
| 371. | Hazard Indices                       | Step   | HZA     | 1964          | Hazard indices measure loss potential due to fire, explosion, and chemical reactivity hazards in the process industries. Can be useful in general hazard identification, in assessing hazard level for certain well-understood hazards, in the selection of hazard reduction design features for the hazards reflected in the index, and in auditing an existing plant.  | Originally developed primarily for insurance purposes and to aid in the selection of fire protection methods.  |                         |   |   | 3 |   |   |   |   |         |             |   | chemical, nuclear      | x  |    |            |   |   | <ul style="list-style-type: none"> <li>[Leveson, 1995]</li> </ul>   |

| 372. | HAZid (Hazard Identification)        | Tab    | HZI     | 1993 or older | Modification of HAZOP especially to be used for identification of human failures. It has an additional first column with some guidewords to lead the keywords.   |  |                         |   | 3 |   |   |   |   |   |         |             |   | oil&gas, chemical, ATM |    |    | x          |   |   | <ul style="list-style-type: none"> <li>[MUFTIS3.2-I, 1996]</li> </ul>   |
| 373. | HAZOP (Hazard and Operability study) | Tab    | HZA     | 1974          | Group review using structured brainstorming to identify and assess potential hazards. The group of experts starts with a list of tasks or functions, and next uses keywords such as NONE, REVERSE, LESS, LATER THAN, PART OF, MORE. Aim is to discover potential hazards, operability problems and potential deviations from intended operation conditions. Finally, the group of experts establishes the likelihood and the consequences of each hazard and identifies potential mitigating measures. | Began with chemical industry in the 1960s. Analysis covers all stages of project life cycle. In practice, the name HAZOP is sometimes (ab)used for any “brainstorming with experts to fill a table with hazards and their effects”. Many variations or extensions of HAZOP have been developed, see e.g. AEMA, EOCA, FPTN, HAZid, Human HAZOP, HzM, MHD, PHEA, PHECA, SHARD (or CHAZOP), SCHAZOP, SUSI, WSA. |                         |   | 3 |   | 6 |   |   |   |         |             | chemical, nuclear, healthcare, ATM, rail, oil&gas | x                      | x  | x  |            |   | <ul style="list-style-type: none"> <li>[Kirwan &amp; Ainsworth, 1992]</li> <li>[Kirwan, Part 1, 1998]</li> <li>[Leveson, 1995]</li> <li>[MUFTIS3.2-I, 1996]</li> <li>[Reese &amp; Leveson, 1997]</li> <li>[ΣΣ93, ΣΣ97]</li> <li>[Storey, 1996]</li> <li>[CAA-RMC93-1]</li> <li>[CAA-RMC93-2]</li> <li>[Foot, 1994]</li> <li>[Kennedy &amp; Kirwan, 1998]</li> <li>[Kletz, 1974]</li> <li>[Villemeur, 1991]</li> </ul> |   |
| 374. | HBN (Hierarchical Bayesian Network)  | Stat   | Mod     | 2002          | HBN is an extension of BBN and consists of two parts. The structural part contains the variables of the network and describes the ‘part-of relationships’ and the probabilistic dependencies between them. The part-of relationships in a structural part may be illustrated either as nested nodes or as a tree hierarchy. The second part of a HBN, the probabilistic part, contains the conditional probability tables that quantify the links introduced at the structural part.                   |  |                         |   |   | 4 | 5 |   |   |   |         |             |   | aviation, electronics  | x  | x  | x          | x | x   | <ul style="list-style-type: none"> <li>[FlachGyftodimos, 2002]</li> <li>[Gyftodimos &amp; Flach, 2002]</li> <li>[Kardes, 2005]</li> </ul> |
| 375. | HCA (Human Centred Automation)       | Gen    | Des     | 1991          | Design and development concept. Can be used to study whether explicit information on the actions of the plant automation system improves operator performance when handling plant disturbances caused by malfunctions in the automation system.  |  |                         |   |   |   |   |   | 7 |   |         |             |   | nuclear, defence       |    |    | x          |   |   | <ul style="list-style-type: none"> <li>[Kirwan et al, 1997]</li> <li>[Kirwan_HCA]</li> <li>[Skjerve HCA]</li> </ul>                       |

| 376. | HCAS<br>(Hazard Classification and Analysis System) | Dat    | Dat              | 2006 | HCAS is a taxonomy for the identification and communication of hazard sources and sub-sources for UAS (Unmanned Aircraft Systems) operations. The system-level taxonomy comprises the four main hazard sources of UAS, Airmen, Operations and Environment and their interactions as well as the constituent sub-sources. There are approximately 100 elements in the HCAS taxonomy.  | HCAS was developed for the U.S. National Airspace System (NAS) by researchers at Rutgers University through a cooperative agreement with the Federal Aviation Administration (FAA). The HCAS taxonomy may serve as a link between the RCFE and actual event analysis. Whereas the RCFE represents a top-down safety analysis, the HCAS represents a “bottom-up” safety analysis. |                         |   | 3 |   |   |   |   |   |         |             | (aviation)        | x      |        | x      | x          |  |   | <ul style="list-style-type: none"> <li>• [FAA UAS SMS]</li> <li>• [Luxhoj, 2009]</li> <li>• [Oztekin &amp; Luxhoj, 2008]</li> </ul> |
| 377. | HCR<br>(Human Cognitive Reliability model)          | Math   | HRA              | 1984 | Method for determining probabilities for human errors after trouble has occurred in the time window considered. Probability of erroneous action is considered to be a function of a normalised time period, which represents the ratio between the total available time and the time required to perform the correct action. Different time-reliability curves are drawn for skill-based, rule-based and knowledge-based performance.  | Developed in nuclear industry by G.W. Hannaman et al. Not considered as very accurate. See also SRK.   |                         |   |   |   | 5 |   |   |   |         |             | nuclear, chemical |        |        | x      |            |  | <ul style="list-style-type: none"> <li>• [Humphreys, 1988]</li> <li>• [Kirwan, 1994]</li> <li>• [MUFTIS3.2-I, 1996]</li> <li>• [Hannaman et al., 1984]</li> </ul> |   |
| 378. | HEA<br>(Human Error Analysis)                       | Gen    | HRA<br>,<br>Task |      | Method to evaluate the human interface and error potential within the human /system and to determine human-error- related hazards. Many techniques can be applied in this human factors evaluation. Contributory hazards are the result of unsafe acts such as errors in design, procedures, and tasks. This analysis is used to identify the systems and the procedures of a process where the probability of human error is of concern. The concept is to define and organise the data collection effort such that it accounts for all the information that is directly or indirectly related to an identified or suspected problem area. This analysis recognises that there are, for practical purposes, two parallel paradigms operating simultaneously in any human/machine interactive system: one comprising the human performance and the other, the machine performance. The focus of this method is to isolate and identify, in an operational context, human performance errors that contribute to output anomalies and to provide information that will help quantify their consequences. | Human Error Analysis is appropriate to evaluate any human/machine interface.   |                         |   | 3 | 5 |   |   |   |   |         |             | all               | x      |        | x      | x          |  | <ul style="list-style-type: none"> <li>• [FAA AC431]</li> <li>• [FAA00]</li> <li>• [HEA practice]</li> <li>• [HEA-theory]</li> <li>• [ΣΣ93, ΣΣ97]</li> </ul>      |   |

HEDAD-O (Operator) provides a source of data to evaluate the extent to which equipment having an interface with operators meets human performance requirements and human engineering criteria.  | Developed by FAA.   |                         |   |   |   |   | 5 |   |   |         |             | defence  | x      |        | x      |            |  | <ul style="list-style-type: none"> <li>[FAA HFW]</li> <li>[HEDADM]</li> <li>[HEDADO]</li> </ul>   |
| 382. | HEDGE<br>(Human factors Engineering Data Guide for Evaluation) | Gen          | Val?             | 1983                | HEDGE is a comprehensive T&E (Test and Evaluation) procedural manual that can be used as a T&E method. It provides the HE (human engineering) practitioner with explanations of methods and sample checklists for evaluating system design and performance. The purpose of the information in HEDGE is to expand test capabilities in considering the human element. It will provide a strategy for viewing an item which is undergoing testing from the standpoint of the soldier who must ultimately operate, maintain, or otherwise utilise it. | Developed by Carlow Associates.   |                         |   |   |   |   |   | 6 |   |         |             | defence  |        |        |        | x          |  | <ul style="list-style-type: none"> <li>[FAA HFW]</li> <li>[MIL-HDBK, 1999]</li> <li>[US Army, 1983]</li> </ul>  |

Makes use of HAMSTERS (Human-centered Assessment and Modelling to Support Task-Engineering for Resilient Systems) notation to represent human activities in a hierarchical way. |                         |   |   | 3 | 4 | 5 |   |   |         |             | space                              | x      |        | x      |            |   |  | <ul style="list-style-type: none"> <li>• [Fayollas et al, 2015]</li> <li>• [Martinie et al, 2016]</li> </ul> |
| 384. | HEERAP<br>(Human Engineering and Ergonomics Risk Analysis Process) | Tab    | HZA, Mit | 2008 | HEERAP is a process that aims at identifying and assessing human injury risks, and at providing guidance on design solutions to mitigate the risks. The process includes determining human interface design requirements, followed by risk analysis, and development of risk mitigation strategies. The risk results are visualised in a Human Injury Risk Matrix.  | Developed by L. Avery et. al.   |                         | 2 |   |   |   | 5 | 6 |   |         |             | (defence), (navy)                  |        |        | x      |            |   |  | <ul style="list-style-type: none"> <li>• [Geiger et al, 2008]</li> </ul>                                     |
| 385. | Heinrich's Pyramid   | Stat   | Par      | 1931 | Heinrich's Pyramid is a depiction of Heinrich's Law that says: for every accident that causes a major injury, there are 29 accidents that cause minor injuries and 300 accidents that cause no injuries. This is then used to estimate accident frequencies based on incident frequencies.  | Also called The Accident Triangle. See also Domino Theory.  |                         |   |   |   |   | 5 |   |   |         |             | ATM, chemical, nuclear, healthcare |        |        |        |            | x |  | <ul style="list-style-type: none"> <li>• [Heinrich, 1931]</li> </ul>   |
| 386. | HEIST<br>(Human Error Identification in Systems Tool)              | Tab    | HRA      | 1994 | HEIST can be used to identify external error modes by using tables that contain various error prompt questions. There are eight tables in total, under the headings of Activation/Detection; Observation/Data collection; Identification of system state; Interpretation; Evaluation; Goal selection/Task definition; Procedure selection and Procedure execution. The analyst applies each table to each task step from an HTA and determines whether any errors are credible. For each credible error, the analyst then records the system cause or psychological error mechanism and error reduction guidelines (which are all provided in the HEIST tables) and also the error consequence. | HEIST was developed by Barry Kirwan as a component of HERA. According to [Stanton et al., 2006] it is nuclear domain specific.  |                         |   | 3 |   |   |   |   |   |         |             | nuclear                            |        |        | x      |            |   |  | <ul style="list-style-type: none"> <li>• [Kirwan, 1994]</li> <li>• [Stanton et al, 2006]</li> </ul>          |
| 387. | HEMECA<br>(Human Error Mode, Effect and Criticality Analysis)      | Tab    | HRA      | 1989 | A FMECA-type approach to Human Error Analysis. It uses a HTA (Hierarchical Task Analysis) followed by error identification and error reduction. The PSF (Performance Shaping Factors) used by the analyst are primarily man-machine interface related, e.g. workplace layout, information presentation, etc. Typically, an FMEA approach identifies many errors, primarily through detailed consideration of these PSF in the context of the system design, in relation to the capabilities and limitations of the operator, based on Ergonomics knowledge. Only those errors that are considered to be probable within the lifetime of the plant are considered further.                       |   |                         | 2 | 3 |   |   | 5 |   |   |         |             | no-domain-found                    |        |        | x      |            |   |  | <ul style="list-style-type: none"> <li>• [Kirwan, Part 1, 1998]</li> </ul>                                   |

| 388. | HERA or HERA-JANUS (Human Error in ATM Technique)                      | Step   | HRA, Ret | 2000          | HERA-JANUS is a method of human error identification developed by Eurocontrol for the retrospective diagnosis during ATM system development. It places the air traffic incident in its ATM context by identifying the ATC behaviour, the equipment used and the ATC function being performed. It identifies the root causes of human errors in aviation accidents/ incidents and associated contextual factors by selecting appropriate 'error types' from the literature, and shaping their usage within a conceptual framework. This conceptual framework includes factors to describe the error, such as error modes and mechanisms and factors to describe the context, e.g. when did the error occur, who was involved, where did it occur, what tasks were being performed? | HERA is TRACER for European use. JANUS is named for the Roman two-headed god of gates and doorways. HERA was renamed HERA-JANUS following harmonisation activities with the FAA. See also HEIST.  |                         |   | 3 |   |   |   |   |   |         |             |        |        |        |        |            |  | <ul style="list-style-type: none"> <li>[Isaac et al, 2003]</li> <li>[Isaac et al, 1999]</li> <li>[Isaac &amp; Pounds, 2001] provides pros and cons compared to HFACS</li> <li>[Kirwan, Part 2, 1998]</li> <li>[Shorrock, 2001]</li> <li>[FAA HFW]</li> <li>[GAIN ATM, 2003]</li> </ul> |
| 389. | HERMES (Human Error Reliability Methods for Event Sequences)           | Dyn    | HFA, Ret | 1996          | HERMES aims to include human factors in safety assessment studies. It is based on: 1. A cognitive simulation model (COSIMO), which assumes that the operator carries out, dynamically and interactively with the plant, the loop "detection-diagnosis-planning-action"; the cognitive processes are controlled by the effectiveness of the gathered information. 2. A classification scheme of erroneous behaviour, correlated to these theories. 3. A model of the functional response of the plant, based on analytical and numerical treatment of differential equations and on the criteria of FMEA. 4. A method based on DYLAM for structuring the interaction of the models of cognition and of plants and for controlling the dynamic evolution of events.                 | Can be used for retrospective and prospective studies. See also COSIMO and DYLAM.   |                         |   |   | 4 |   |   |   |   |         |             |        |        |        |        |            |  | <ul style="list-style-type: none"> <li>[Cacciabue et al, 1996]</li> </ul>  |
| 390. | HERTES (Human Error Reduction Technique for the Evaluation of Systems) | Step   | HRA      | 2005          | HERTES seeks to establish the hazards and risks associated with human error, and classify these in an order of risk. It includes guidance on how to identify, assess and classify human hazards, and guidance on how different types of hazard are to be addressed in a project setting – by setting human error requirements on the project for elimination, reduction or mitigation – and the ways in which these can be shown to have been achieved.   | HERTES is an internally devised approach in NATS, as an answer to needs to include Human Factors assurance in Safety Engineering techniques.  |                         |   |   |   | 5 | 6 |   |   |         |             |        |        |        |        |            |  | <ul style="list-style-type: none"> <li>[Clark et al., 2008]</li> </ul>   |
| 391. | HESC (Human Engineering Simulation Concept)                            | RTS    | HRA      | 2000 or older | HESC aims at using mock-ups and simulators in support of human engineering analysis, design support, and test and evaluation.   | May be used by the procuring activity to assist and assess simulation approaches when there is a need to resolve potential human performance problems, particularly where government facilities, models, data or participants are required. |                         | 2 |   |   |   |   |   |   |         |             |        |        |        |        |            |  | <ul style="list-style-type: none"> <li>[FAA HFW]</li> </ul>  |

| 396. | HFA<br>(Human Factors Analysis)                             | Gen    | HFA<br>,<br>Task |      | Human Factors Analysis represents an entire discipline that considers the human engineering aspects of design. There are many methods and techniques to formally and informally consider the human engineering interface of the system. There are specialty considerations such as ergonomics, bio-machines, anthropometrics. The Human Factors concept is the allocation of functions, tasks, and resources among humans and machines. The most effective application of the human factors perspective presupposes an active involvement in all phases of system development from design to training, operation and, ultimately, the most overlooked element, disposal. Its focus ranges from overall system considerations (including operational management) to the interaction of a single individual at the lowest operational level. However, it is most commonly applied and implemented, from a systems engineering perspective, to the system being designed and as part of the SHA. | Human Factors Analysis is appropriate for all situations where the human interfaces with the system and human-related hazards and risks are present. The human is considered a main sub-system.   |                         |   | 3 |   | 5 | 6 |   |   |                               | all         | x      |        | x      | x      |   | <ul style="list-style-type: none"> <li>• [FAA AC431]</li> <li>• [FAA00]</li> <li>• [ΣΣ93, ΣΣ97]</li> </ul> |
| 397. | HFACS<br>(Human Factors Analysis and Classification System) | Tab    | HRA              | 1997 | Human factors taxonomy. HFACS examines instances of human error as part of a complex productive system that includes management and organisational vulnerabilities. HFACS distinguishes between the "active failures" of unsafe acts, and "latent failures" of preconditions for unsafe acts, unsafe supervision, and organisational influences.  | It is based on James Reason's Swiss cheese model of human error in complex systems. Developed by Scott Shappell (Civil Aviation Medical Institute) and Doug Wiegmann (University of Illinois). Originally developed for the US navy for investigation of military aviation incidents; a Maintenance Extension is referred to as HFACS-ME and is similar to MEDA. Is currently being used by FAA to investigate civil aviation incidents. A version adapted for the railroad industry is HFACS-RR. |                         |   | 3 |   |   |   |   | 8 | defence, navy, aviation, rail |             |        | x      |        | x      | <ul style="list-style-type: none"> <li>• [Isaac &amp; Pounds, 2001] provides pro-s and con's compared to HERA</li> <li>• [FAA HFW]</li> <li>• [Shappell &amp; Wiegman, 2000]</li> <li>• [Wiegman et al, 2000]</li> <li>• [GAIN AFSA, 2003]</li> <li>• [GAIN ATM, 2003]</li> </ul> |  |
| 398. | HFAM<br>(Human Factors Analysis Methodology)                | Step   | Org,<br>HRA      | 1993 | HFAM is comprised of 20 groups of factors that are subdivided into three broad categories: 1) management level factors; 2) operational level generic factors; 3) operational level job specific factors. HFAM first invokes a screening process to identify the major areas vulnerable to human error; the generic and appropriate job-specific factors are then applied to these areas. The problems that are identified ultimately reflect failures at the management control level. Corresponding management-level factors would then be evaluated to identify the nature of the management-based error (latent errors).   | Management-level factors fall into various categories, including 1) those that can be specifically linked to operational-level factors; 2) those that are indicators of the quality of safety culture and therefore can affect the potential for both errors and violations; 3) those that reflect communication of information throughout the organisation, incl the capability for learning lessons from operational experience based on various forms of feedback channels.                    |                         |   | 3 |   | 5 |   |   |   | (nuclear), (chemical)         |             |        | x      |        | x      | <ul style="list-style-type: none"> <li>• [Pennycook &amp; Embrey, 1993]</li> </ul>  |  |

| 399. | HF-Assessment Method (Human Factors Assessment Method) | Tab    | HFA     | 2003 | HF-Assessment Method can be used for systematically reviewing both the process of how Human Factors have been integrated into the design and operation of control rooms and for evaluating the results of this process. The method can be used under the development of new control rooms, modifications, upgrades or evaluation of existing control rooms. It consists of seven revision checklists: One checklist of Questions and references that cover minimum requirements to documentation; One checklist of Questions and references that cover minimum requirements to all phases; and Five checklists of Questions and references that cover minimum requirements to each phase. | Was developed by HFS (Human Factors Solutions) for the PSA to allow them to assess how well operating companies comply with the Health, Safety and Environment (HSE) Regulations. The tool is for use by the Norwegian Petroleum Directorate (NPD) and the petroleum industry. |                         | 2 |   |   | 5 |   |   |   |         |             | oil&gas                                  |        |        | x      |            |   |  | • [HFS, 2003]   |
| 400. | HFC (Human Factors Case)                               | Int    | HFA     | 2002 | A Human Factors Case is a framework for human factors integration, similar to a Safety Case for Safety Management. The approach has been developed to provide a comprehensive and integrated approach that the human factors aspects are taken into account in order to ensure that the system can safely deliver desired performance. Human Factors issues are classified according to six categories: 1. Working Environment; 2. Organisation and Staffing; 3. Training and Development; 4. Procedures, Roles and Responsibilities; 5. Teams and Communication; 6. Human and System. Subsequently, an Action Plan is made to address these issues.                                      | Developed by Eurocontrol.  |                         | 2 | 3 |   | 5 | 6 |   |   |         |             | ATM                                      |        |        |        | x          |   |  | • [HFC, 2004]<br>• [Barbarino, 2001]<br>• [Barbarino, 2002]                         |
| 401. | HHA (Health Hazard Assessment)                         | Step   | Hzi     | 1981 | The method is used to identify health hazards and risks associated within any system, sub-system, operation, task or procedure. The method evaluates routine, planned, or unplanned use and releases of hazardous materials or physical agents.   | The technique is applicable to all systems which transport, handle, transfer, use, or dispose of hazardous materials of physical agents.   |                         |   | 3 |   |   |   |   |   |         |             | defence, navy, healthcare                | x      |        |        |            | x |  | • [FAA00]<br>• [FAA tools]<br>• [ΣΣ93, ΣΣ97]  |

| 402. | HIP Model (Human Information Processing Model)         | Int    | HFA     | 1984 | This is a framework for modelling human cognitive process through a series of mental operations beginning with sensory stimuli and ending with response execution. Consists of: 1) Sensory store, which converts physical phenomena into neural manifestations. 2) Pattern recognition, which maps the physical codes of the sensory stores into meaningful elements. 3) Decision/ response selection, which depends on the options available. 4) Response execution, which is initiated by the response selection. 5) Attention Resources, which can be viewed as a limiting factor for the last three stages.   | Developed by C.D. Wickens.   |                         |   |   | 4 |   |   |   |   |         |             | food, management, road, ATM, electronics |        |        |        | x          |   |  | • [Wickens & Flach, 1988]<br>• [Wickens & Hollands, 1999]<br>• [Leiden et al, 2001] |

Can be used to estimate effects of human performance on a system before development/ modification.   | Originally conceived in 1970 by Robert Wherry Jr. (Navy at Point Magu), but has undergone a series of major upgrades. Version IV became available in 1989. |                         |   |   |   | 4 |   |   |   |         |             | defence, navy    |            |        | x      |            |   |  | <ul style="list-style-type: none"> <li>[FAA HFW]</li> <li>[HOS user's guide, 1989]</li> <li>[Morrison, 2003]</li> </ul>      |
| 408. | How-How Diagram  | Stat   | Mit      | 1973          | A How-How Diagram is a Tree Diagram where each child is determined by asking 'how' the parent can be achieved. It is thus useful for creating solutions to problems. Steps: 1) Place the solution to the left side of a paper; 2) Identify the initial steps needed to implement the solution and write them in the appropriate blanks to the right of the solution; 3) Consider each step individually, breaking it down into its detailed constituent stages by repeatedly asking how it might be achieved; 4) The process continues until each step has been drawn out until its logical limit; 5) examining the complete diagram for recurring elements, which tend to indicate the most crucial stages in the process of implementation. | Also referred to as Relevance Tree. See also Why-Why diagram.  |                         |   |   |   | 4 |   |   |   |         |             | food, management | x          |        |        |            |   |  | <ul style="list-style-type: none"> <li>[IE, How-How]</li> <li>[Futures Group, 1994]</li> <li>[Switalski, 2003]</li> </ul>    |

| 410. | HPES<br>(Human Performance Enhancement System)    | Stat      | Ret          | 1990                | The HPES method is a systematic process for understanding how the event happened, why the behaviour occurred and what additional factors contributed to the event. HPES uses event and causal factor charting, in which the tools of barrier analysis, change analysis and cause and effect analysis have been graphically incorporated into the same chart. The integrated chart shows the direct causes, the root causes, the contributing causes, and the failed barriers, with their interconnections and dependencies.  | HPES was developed by Institute of Nuclear Power Operations (INPO) in 1990. The method aims at identification of human performance issues. Methods derived from HPES include: K-HPES (Korean version), J-HPES (Japanese version), UK-HPES (UK version), Man-Technology-Organisation Investigation (MTO) (Swedish version), CAS-HPES (computer-aided system for K-HPES), HPIP, AEB, PRCAP, CERCA. |                         |   |   |   |   |   |   |   |         | 8           | nuclear |         |        | x      |            |  |   | • [Ziedelis & Noel, 2011]                |
| 411. | HPIP<br>(Human Performance Investigation Process) | Int       | HRA<br>, Ret | 1994                | HPIP aims at investigation of events that involve human performance issues at nuclear facilities. It is a suite of six tools: 1) Events and Causal Factors Charting: - Helps to plan an accident Investigation. 2) SORTM - A guide to HPIP Modules used to assist investigation planning and fact collection. 3) Barrier Analysis – To identify human performance difficulties for root cause analysis 4) HPIP Modules - Identifies important trends or programmatic system weaknesses. 5) Change Analysis – Allows understanding of the event and ensures complete investigation and accuracy of perceptions. 6) Critical Human Actions Profile (CHAP) - Similar to change analysis, CHAP provides an understanding of the event and ensures complete investigation and accuracy of perceptions | HPIP was developed for the US Nuclear Regulatory Commission and the safety management factors in the Management Oversight & Risk Tree (MORT) of the US Department of Energy.   |                         |   | 2 | 3 | 4 | 5 |   |   |         |             |         | nuclear |        |        | x          |  |   | • [FAA HFW]<br>• [Ziedelis & Noel, 2011] |
| 412. | HPLV<br>(Human Performance Limiting Values)       | Math<br>? | Val          | 1990                | HPLVs are used as dependency ‘bounding probabilities’ for human error outsets. They represent a quantitative statement of the analyst’s uncertainty as to whether all significant human error events have been adequately modelled in the fault tree. Special attention to (in)dependence of human errors. It is important to note that HPLVs are not HEPs (Human Error Probabilities); they can only be used to limit already modelled HEPs once direct dependence has been considered.   | Developed by Kirwan et al. Relation with Fault Trees. JHEDI applies HPLV to fault trees. See also Bias and Uncertainty assessment. See also Uncertainty Analysis.  |                         |   |   |   |   | 5 |   |   |         |             | nuclear |         |        | x      |            |  | • [Kirwan, 1994]  |  |
| 413. | HPM<br>(Human Performance Modelling)              | Gen       | HRA          | 1940<br>or<br>older | Human performance models are abstractions, usually mathematical or computational, that attempt to explain or predict human behaviour in a particular domain or task. They can be used, e.g., to examine latent design flaws that induce human error, to compare development options, to define procurement needs or strategies, to examine human interactions with existing and proposed technical systems, to examine aspects of the task environment, equipment and procedures. The model mechanisms can be anything from a simple mathematical formula, to complex computerised 3-D graphics simulations.   | Human performance is defined as the accomplishment of a task in accordance with agreed upon standards of accuracy, completeness, and efficiency. Many specific techniques and tools are available.   |                         |   |   |   | 4 |   |   |   |         |             | all     |         |        | x      |            |  | • [Leiden & Best, 2005]<br>• [Foyle et al, 2005]<br>• [Pew, 2008]<br>• [Corker et al, 2005]<br>• [Blom & Stroeve et al, 2002]<br>• [Blom & Stroeve & Daams & Nijhuis, 2001] |  |

| 414. | HPRA (Human Performance Reliability Analysis) | Gen    | HRA      |               | Consists of an analysis of the factors that determine how reliably a person will perform within a system or process. General analytical methods include probability compounding, simulation, stochastic methods, expert judgement methods, and design synthesis methods.   | Among published HPRA methods are THERP, REHMS-D, SLIM-MAUD, MAPPS.  |                         |   |   |   | 4 | 5 |   |   |         |             | all               |        |        | x      |            |  |  | • [MIL-HDBK, 1999]  |
| 415. | HRA (Human Reliability Analysis)              | Gen    | HRA      | 1952          | Human Reliability Analysis is a generic name for methods to assess factors that may impact human reliability in a probabilistic risk analysis for the operation of a socio-technical system.   |   |                         |   |   | 3 | 5 |   |   |   |         |             | all               |        |        |        | x          |  |  | • [FAA00]<br>• [Kirwan, 1994]<br>• [Hollnagel, 1993]<br>• [Pyy, 2000]<br>• [NEA, 1998]<br>• [ΣΣ93, ΣΣ97]        |
| 416. | HRAET (Human Reliability Analysis Event Tree) | Stat   | HRA      | 1983          | Tool used for THERP. Is a simpler form of event tree, usually with diagonal line representing success, and individual branches leading diagonally off the success diagonal representing failure at each point in the task step.  | Can also be used for maintenance errors. See also THERP.  |                         |   |   |   | 4 | 5 |   |   |         |             | nuclear, maritime |        |        |        | x          |  |  | • [Kirwan & Ainsworth, 1992]<br>• [Kirwan & Kennedy & Hamblen]<br>• [MUFTIS3.2-I, 1996]                         |
| 417. | HRMS (Human Reliability Management System)    | Int    | HRA      | 1989          | The HRMS is a fully computerized system dealing with all aspects of the process. It is a quantification module based on actual data, which is completed by the author's own judgments on the data extrapolation to the new scenario/tasks. A PSF (Performance Shaping Factors)-based sensitivity analysis can be carried out in order to provide error-reduction techniques, thus reducing the error likelihood.   | Developed by Kirwan et al. Apparently not in current use or else used rarely. JHEDI is a derivative of HRMS and provides a faster screening technique.  |                         |   |   |   |   |   |   |   | 8       |             | nuclear           |        |        |        | x          |  |  | • [DiBenedetto, 2002]<br>• [Kirwan, 1994]<br>• [Kirwan, Part 1, 1998]<br>• [Seignette, 2002]                    |
| 418. | HSIA (Hardware/Software Interaction Analysis) | Tab    | SwD, HwD | 1991 or older | The objective of HSIA is to systematically examine the hardware/ software interface of a design to ensure that hardware failure modes are being taken into account in the software requirements. Further, it is to ensure that the hardware characteristics of the design will not cause the software to over-stress the hardware, or adversely change failure severity when hardware failures occur. HSIA is conducted through checklists, according to which an answer shall be produced for each identified failure case. Checklists are specific to each analysis and have to take into account the specific requirements of the system under analysis. The analysis findings are resolved by changing the hardware and/or software requirements, or by seeking ESA approval for the retention of the existing design. | HSIA is obligatory on ESA (European Space Agency) programmes and is performed for all functions interfacing the spacecraft and / or other units. The HSIA is generally initiated once the development of the hardware is already finished and the development of the software is not started (or it is at the very beginning of the process). See also Interface Testing. See also Interface Analysis, See also LISA. |                         |   | 3 |   |   |   | 6 |   |         | space       | x                 | x      |        |        |            |  |  | • [Hoegen, 1997]<br>• [Parker et al, 1991]<br>• [Rakowsky]<br>• [SW, 2004]                                      |
| 419. | HSMP (Hybrid-State Markov Processes)          | Math   | Mod      | 1990 or older | Combines deterministic stochastic evolution with switching of mode processes. The Hybrid Markov state consists of two components, an n-dimensional real-valued component, and a discrete valued component. The HSMP is represented as a solution of a stochastic differential or difference equation on a hybrid state space, driven by Brownian motion and point processes. The evolution of the probability density on the hybrid state space is the solution of a partial integro-differential equation.  | Used in e.g. TOPAZ. Numerical evaluation requires elaborated mathematical techniques such as Monte Carlo simulation.  |                         |   |   |   | 4 |   |   |   |         |             | ATM               | x      |        | x      | x          |  |  | • [Krystul et al, 2012]<br>• [Krystul et al, 2007]<br>• [Blom, 2003]<br>• [Blom, 1990]<br>• [MUFTIS3.2-I, 1996] |

| 420. | HSYS<br>(Human System Interactions)           | Stat   | HRA              | 1990                | HSYS provides a systematic process for analyzing Human-System interactions in complex operational settings. It focuses on system interactions from the human's perspective and is built around a linear model (based on Fault Tree principles) of human performance, termed the Input-Action model. According to the model, all human actions involve, to varying degrees, five sequential steps: Input Detection, Input Understanding, Action Selection, Action Planning, and Action Execution. These five steps form branches of the hierarchical tree and have aided in both prospective and retrospective analysis. Based on the Input-Action model, a series of flow charts supported by detailed "topical modules," have been developed to analyze each of the five main components in depth. | HSYS was developed at the Idaho National Engineering Laboratory (INEL). Similar to MORT.   |                         |   |   | 4 |   |   |   |          |  | oil&gas     |        |        | x      |   |  | <ul style="list-style-type: none"> <li>[Harbour &amp; Hill, 1990]</li> <li>[FAA HFW]</li> </ul> |
| 421. | HTA<br>(Hierarchical Task Analysis)           | Stat   | Task             | 1967                | HTA is a method of task analysis that describes tasks in terms of operations that people do to satisfy goals and the conditions under which the operations are performed. The focus is on the actions of the user with the product. This top down decomposition method looks at how a task is split into subtasks and the order in which the subtasks are performed. The task is described in terms of a hierarchy of plans of action.  | First paper on the specification for the method dates from 1967 by Annett and Duncan.  |                         | 2 |   |   |   |   |   |          | ATM, nuclear, defence, navy, energy, chemical, oil&gas, ergonomics |             |        | x      | x      |   | <ul style="list-style-type: none"> <li>[Kirwan &amp; Ainsworth, 1992]</li> <li>[Kirwan, 1994]</li> <li>[Stanton &amp; Wilson, 2000]</li> <li>[Shepherd, 2001]</li> <li>[Kirwan et al, 1997]</li> <li>[Diaper &amp; Stanton, 2004]</li> <li>[Shepherd, 1998]</li> </ul> |   |
| 422. | HTLA<br>(Horizontal Timeline Analysis)        | Tab    | Task<br>,<br>HFA | 1987<br>or<br>older | Investigates workload and crew co-ordination, focusing on task sequencing and overall timing. Is constructed from the information in the VTLA (Vertical Timeline Analysis) to determine the likely time required to complete the task. Usually a graphical format is used, with sub-tasks on the y-axis and time proceeding on the x-axis. The HTLA shows firstly whether the tasks will be achieved in time, and also where certain tasks will be critical, and where bottlenecks can occur. It also highlights where tasks must occur in parallel, identifying crucial areas of co-ordination and teamwork.   | See also VTLA. See also Timeline Analysis. VTLA focuses on crew activities and personnel whereas HTLA focuses on task sequencing and overall timing.   |                         |   | 3 | 4 |   |   |   |          | finance,<br>nuclear  |             |        | x      | x      |   | <ul style="list-style-type: none"> <li>[Kirwan &amp; Kennedy &amp; Hamblen]</li> <li>[Kirwan, 1994]</li> <li>[Task Time]</li> </ul>  |   |
| 423. | HTRR<br>(Hazard Tracking and Risk Resolution) | Dat    | Dat,<br>Val      | 1985                | Method of documenting and tracking hazards and verifying their controls after the hazards have been identified by analysis or incident. The purpose is to ensure a closed loop process of managing safety hazards and risks. Each program must implement a Hazard Tracking System (HTS) to accomplish HTRR.   | HTRR applies mainly to hardware and software-related hazards. However, it should be possible to extend the method to also include human and procedures related hazards, by feeding these hazards from suitable hazard identification techniques. |                         |   |   |   |   |   | 8 | aviation | x  | x           |        |        |        | <ul style="list-style-type: none"> <li>[FAA00]</li> <li>[FAA tools]</li> <li>[FAA SSMP]</li> <li>[MIL-STD 882B]</li> <li>[NEC, 2002]</li> </ul> |  |   |

| 430. | HzM (Multilevel HAZOP) | Tab    | HzA     | 2001 | HzM maintains the HAZOP approach, but breaks down the analysis in two directions: vertical (hierarchical breakdown of each procedure in an ordered sequence of steps) and horizontal (each step is further broken down into the three logical levels operator, control system and plant/ process). This allows recording how deviations may emerge in different logical levels and establishing specific preventive/ protective measures for each.  | Combined use with HEART, THERP and Event trees possible.                                 |                         |   |   | 3 | 4 |   | 6 |   |         | chemical    | x   |        | x      |        |            |  | <ul style="list-style-type: none"> <li>• [Cagno &amp; Acron &amp; Mancini, 2001]</li> </ul>  |  |
| 431. | i* Model Analysis      | Stat   | Des     | 1994 | i* is an approach originally developed to model information systems composed of heterogeneous actors with different, often-competing goals that nonetheless depend on each other to undertake their tasks and achieve these goals. The i* approach supports the development of 2 types of system model. The first is the Strategic Dependency (SD) model, which provides a network of dependency relationships among actors. The opportunities available to these actors can be explored by matching the depender who is the actor who wants” and the dependee who has the ability”. The dependency link indicates that one actor depends on another for something that is essential to the former actor for attaining a goal. The second type of i* model is the Strategic Rationale (SR) model, which provides an intentional description of processes in terms of process elements and the relationships or rationales linking them. A process element is included in the SR model only if it is considered important enough to affect the achievement of some goal. The SR model has four main types of nodes: goals, tasks, resources and softgoals. |  |                         | 2 |   |   |   |   |   |   | ATM     | x           | x   |        |        |        |            | <ul style="list-style-type: none"> <li>• [Maiden &amp; Kamdar &amp; Bush, 2005]</li> <li>• [Yu, 1994]</li> </ul> |  |  |

| 432. | IA<br>(Impact Analysis)                        | Gen    | SwD      | 1996          | Prior to modification or enhancement being performed on the software, an analysis is undertaken to identify the impact of the modification or enhancement on the software and also identify the affected software systems and modules. Two forms are traceability IA and dependency IA. In traceability IA, links between requirements, specifications, design elements, and tests are captured, and these relationships can be analysed to determine the scope of an initiating change. In dependency IA, linkages between parts, variables, logic, modules etc. are assessed to determine the consequences of an initiating change. Dependency IA occurs at a more detailed level than traceability IA.  | Defined by S.A. Bohner and R.S. Arnold. Software maintenance phase. Sometimes referred to as Change Impact Analysis or Software Change Impact Analysis. |                         |   | 3 |   |   |   |   |   |         |             | software   |        | x      |        |            |   |  | <ul style="list-style-type: none"> <li>• [EN 50128, 1996]</li> <li>• [Rakowsky]</li> </ul>   |

| 435. | IDDA<br>(Integrated Dynamic Decision Analysis) | Dyn    | Mod, OpR | 1994 or older | IDDA develops the sequences of events from the point of view both of the logical construction, and of the probabilistic coherence. The system description has the form of a binary chart, where the real logical and chronological sequence of the events is described; the direction of each branch is characterised by a probability of occurrence that can be modified by the boundary conditions, and in particular by the same development of the events themselves (probabilities conditioned by the events dynamic). At the end of the analysis, the full set of the possible alternatives in which the system could evolve is obtained. These alternatives represent a "partition" since they are mutually exclusive; they are all and the sole possible alternatives, thus allowing the method to guarantee the completeness and the coherence of the analysis. | Developed by R. Galvagni. IDDA is based on an enhanced form of dynamic event tree.  |                         |   |   | 4 | 5 |   |   |   |         |             | nuclear, chemical, oil&gas                           | x      |        |        |            |   |  | <ul style="list-style-type: none"> <li>• [Demichela &amp; Piccinini, 2003]</li> <li>• [Galvagni et al, 1994]</li> <li>• [Piccinini et al, 1996]</li> </ul> |

| 436. | IDEF (Integrated Computer-Aided Manufacturing Definition or Integration DEFinition)   | Int    | Mod     | 1981 | Method of system modelling that enables understanding of system functions and their relationships. Using the decomposition methods of structural analysis, the IDEF modelling languages define a system in terms of its functions and its input, outputs, controls and mechanisms. IDEF covers a wide range of uses, from functional modeling to data, simulation, object-oriented analysis/design and knowledge acquisition.  | Developed at US Air Force during the 1970s-1980s. IDEF0 is derived from and is the military equivalent to SADT. Currently, IDEF comprises a suite of methods named IDEF0, (Function modelling), IDEF1 (Information Modelling), IDEF1X (Data Modelling), IDEF2 (Simulation Model Design), etc, up to IDEF14 (Network Design); some of these have not been developed further than their initial definition. |                         | 2 |   |   |   |   |   |   |         |             |        |        |        |        |            |  | <ul style="list-style-type: none"> <li>[HEAT overview]</li> <li>[MIL-HDBK, 1999]</li> <li>[Mayer et al., 1992]</li> </ul> |
| 437. | ILCI Loss Causation Model (International Loss Control Institute Loss Causation Model) | Stat   | Mit     | 1985 | The ILCI model focuses on development of performance standards and enforcement of standards to ensure that employees are performing their work in a safe manner. The ILCI model is based on a sequence of events that leads up to an eventual loss. The events in sequential order are, Lack of Control, Basic Causes, Immediate Causes, Incident/Contact, and Loss. Each event has a role in continuing the loss process to its conclusion, the Loss.   | Developed by Mr. Frank E. Bird, Jr. of ILCI in the USA, and based Heinrich's pyramid and his Domino Theory. In 1991, DNV (Det Norske Veritas) bought ILCI rights.   |                         |   |   |   |   |   |   | 6 |         |             |        |        |        |        |            |  | <ul style="list-style-type: none"> <li>[Kjellen, 2000]</li> <li>[Storbakken, 2002]</li> </ul>                             |

Embrey.   |                         | 2 |   |   |   |   |   |   |         |             |        |        |        |        |            |  | <ul style="list-style-type: none"> <li>[Kirwan, Part 1, 1998]</li> </ul>  |
| 439. | Importance Sampling   | Math   | Val     | 1980 | Technique to enable more frequent generation of rare events in Monte Carlo Simulation. Rare events are sampled more often, and this is later compensated for.  | Developed by Shanmugan and Balaban. Combine with simulations.   |                         |   |   |   |   | 5 |   |   |         |             |        |        |        |        |            |  | <ul style="list-style-type: none"> <li>[MUFTIS3.2-I, 1996]</li> <li>[Shanmugan&amp;Balaban, 1980]</li> </ul>              |
| 440. | IMPRINT (Improved Performance Research Integration Tool)                              | FTS    | Task    | 1994 | IMPRINT is a stochastic, discrete event, network modeling tool designed to assist in the evaluation of interactions of human users and system technologies through different phases of the system life cycle. A system mission is decomposed into functions, which are further decomposed into tasks. A branching logic determines how the functions and tasks are connected at their respective levels, indicating whether they are repeated, performed simultaneously, serially, or probabilistically. | Developed by Human Research and Engineering Directorate of ARL (Army Research Laboratory). IMPRINT simulates human performance at a larger level of granularity as compared to the cognitive level of ACT-R. See also HPM (Human Performance Modelling). See also MRT (Multiple Resources Theory).  |                         |   |   |   | 4 |   |   |   |         |             |        |        |        |        |            |  | <ul style="list-style-type: none"> <li>[Leiden &amp; Best, 2005]</li> <li>[Salvi, 2001]</li> <li>[Alley, 2005]</li> </ul> |

| 441. | InCAS (Interactive Collision Avoidance Simulator)     | RTS       | Col     | 2000 or older | InCAS is a PC-based interactive simulator for replaying and analysing Airborne Collision Avoidance System (ACAS) during close encounters between aircraft. It is designed for case-by-case incident analysis by investigators. InCAS reads radar data and provides an interface to examine these data in detail, removing any anomalies that may be present. The cleaned data are used to simulate trajectories for each aircraft at one-second intervals and these data are fed into a full version of the logic in the Traffic Alert and Collision Avoidance System, TCAS II (versions 6.04A or 7). | Developed by Eurocontrol.  |   |   |   |   |   |   |   |   |         |             | 8      | ATM, aviation | x                             |        |            |  |  |   | • [GAIN ATM, 2003]                                     |                                |
| 442. | In-Depth Accident Investigation                       | Gen       | Ret     | 1995 or older | Aim is to investigate a severe accident or near-accident on-the-scene. Follows eight generic steps: 1) Securing the scene; 2) Appointing an investigation commission; 3) Introductory meeting, planning the commission's work; 4) Collection of information; 5) Evaluations and organising of information; 6) Preparing the commission's report; 7) Follow-up meeting; 8) Follow-up.  | This method particularly refers to road traffic accidents, but in a general sense, such investigations are done in other domains as well.  |   |   |   |   |   |   |   |   |         |             |        | 8             | road, aviation, ATM, maritime | x      |            |  |  | x | • [Kjellen, 2000]                                      |                                |
| 443. | INEL approach (Idaho National Engineering Laboratory) | Tab       | Org     | 1993          | Safety culture assessment for nuclear industry. Consists of 19 safety culture categories: Individual responsibility; Safe processes; Safety thinking; Safety management; Priority of safety; Safety values; Safety awareness; Teamwork; Pride and commitment; Excellence; Honesty; Communications; Leadership and supervision; Innovation; Training; Customer relations; Procedure compliance; Safety effectiveness; Facilities.  |  |   |   |   |   |   |   |   |   |         |             |        | 8             | nuclear                       |        |            |  |  |   | x  | • [Mkrtychyan & Turcanu, 2012] |

| 444. | Information Hiding or Information Encapsulation       | Step, Gen | Des     | 1972          | Aim is to increase the reliability and maintainability of software or hardware. Encapsulation (also information hiding) consists of separating the external aspects of an object, which are accessible to other objects, from the internal implementation details of the object, which are hidden from other objects. If an internal state is encapsulated it cannot be accessed directly, and its representation is invisible from outside the object.   | Developed by David Parnas. Closely related to object-oriented programming and design. Tools available. Information Hiding is fundamental to division of labour: the participants do not need to know everything about each other's tasks or component. |   |   |   | 3 |   |   |   |   |         |             |        | 6             | manufacturing, security       | x      | x          |  |  |   | • [Bishop, 1990]<br>• [EN 50128, 1996]<br>• [Rakowsky] |                                |

| 446. | Inspections and Walkthroughs   | Gen    | SwD       | 1972          | Aim is to detect errors in some product (mostly a software product) of the development process as soon and as economically as possible. An inspection is the most formal type of group review. Roles (producer, moderator, reader and reviewer, and recorder) are well defined, and the inspection process is prescribed and systematic. During the meeting, participants use a checklist to review the product one portion at a time. Issues and defects are recorded, and a product disposition is determined. When the product needs rework, another inspection might be needed to verify the changes. In a walkthrough, the producer describes the product and asks for comments from the participants. These gatherings generally serve to inform participants about the product rather than correct it. | Effective method of finding errors throughout the software development process. In a Cognitive Walkthrough, a group of evaluators step through tasks, evaluating at each step how difficult it is for the user to identify and operate the system element and how clearly the system provides feedback to that action. Cognitive walkthroughs take into consideration the user's thought processes that contribute to decision making, such as memory load and ability to reason. See also Walk-Through Task Analysis. | 447. | Integrated NASTEP Application (Integrated National Airspace System Technical Evaluation Program Application) | Dat    | Dat, Val  | 2004 or older | This national database contains reports, findings, and mitigation plans from NASTEP audits and assessments. NASTEP is a program that contributes to the periodic review and maintenance of equipment and procedures. The program offers an independent technical review of how well facilities and services meet their intended objectives; how well the maintenance program is executed; and how well customer needs are being met. Data output includes performance and audit reports.  | Maintained by the NAS QA and Performance Group in the Technical Operations Services Management Office.  |                         |   |   |   |   |   | 6 | 7 |         |             | ATM                             | x      |        |        |            | x |  | • [ATO SMS Manual v3.0]<br>• [FAA SMS, 2004] |
| 448. | Integrated Process for Investigating Human Factors   | Step   | HFA, Ret  | 1995          | This tool provides a step-by-step systematic approach in the investigation of human factors. The tool can be applied to accidents or incidents. The process consists of seven steps 1) collect occurrence data, 2) determine occurrence sequence, 3) identify unsafe actions (decisions) and unsafe conditions, and then for each unsafe act (decision) 4) identify the error type or adaptation, 5) identify the failure mode, 6) identify behavioural antecedents, and 7) identify potential safety problems.   | Developed by Transportation Safety Board of Canada. The process is an integration and adaptation of a number of human factors frameworks - SHEL (Hawkins, 1987) and Reason's (1990) Accident Causation and generic error-modelling system (GEMS) frameworks, as well as Rasmussen's Taxonomy of Error (1987).   |                         | 2 | 3 | 4 |   |   |   |   |         |             | (aviation), (ATM)               |        |        |        | x          |   |  | • [GAIN AFSA, 2003]                          |

| 449. | INTENT                   | Tab    | HRA     | 1991          | Is aimed at enabling the incorporation of decision-based errors into PSA, i.e. errors involving mistaken intentions, which appears to include cognitive errors and rule violations, as well as EOCs. Four categories of error of intention are identified: action consequence; crew response set; attitudes leading to circumvention; and resource dependencies. A set of 20 errors of intention (and associated PSF (Performance Shaping Factor)) are derived, and quantified using seven experts. The methodological flow for INTENT involves six stages: Compiling errors of intention, quantifying errors of intention, determining human error probabilities (HEP) upper and lower bounds, determining PSF and associated weights, determining composite PSF, and determining site specific HEP's for intention. | Developed by Gertman et al.   |                         |   |   | 3 | 4 | 5 |   |   |         |             | nuclear                      |        |        | x      |            |  |  | • [Kirwan, Part 1, 1998] |
| 450. | Interdependence Analysis | Stat   | SwD     | 1967          | Aim is to examine the software to determine the interdependence among Computer Software Components (CSCs), modules, tables, variables, etc. Elements of software that directly or indirectly influence Safety Critical Computer Software Components (SCCSCs), e.g. shared memory blocks used by two or more SCCSCs, are also identified as SCCSCs, and as such should be analyzed for their undesired effects. The inputs and outputs of each SCCSC are inspected and traced to their origin and destination.   | The term Interdependence analysis was coined by Beale et al, in 1967, and reappeared in the title of a monograph by Boyce et al., in 1974.  |                         |   |   | 4 |   |   |   |   |         |             | software                     |        | x      |        |            |  | • [FAA00]<br>• [Duncan & Dunn, 1999]<br>• [Beale et al, 1967]<br>• [Boyce et al, 1974] |                          |
| 451. | Interface Analysis       | Step   | Hzi     | 1995 or older | The analysis is used to identify hazards due to interface incompatibilities. The methodology entails seeking those physical and functional incompatibilities between adjacent, interconnected, or interacting elements of a system, which, if allowed to persist under all conditions of operation, would generate risks.   | Interface Analysis is applicable to all systems. All interfaces should be investigated; machine-software, environment- human, environment-machine, human-human, machine-machine, etc. See also Interface Testing. See also HSIA. See also LISIA. See also SHEL. |                         |   | 3 |   |   |   |   |   |         |             | electronics, avionics, space | x      | x      |        |            |  | • [FAA00]<br>• [Leveson, 1995]<br>• [Rakowsky]<br>• [ΣΣ93, ΣΣ97]                       |                          |
| 452. | Interface Surveys        | Gen    | Dat     | 1977          | Interface surveys are a group of information collection methods that can be used to gather information about specific physical aspects of the person-machine interface at which tasks are carried out. Examples of these techniques are Control/Display Analysis; Labelling Surveys; Coding Consistency Surveys; Operator modifications surveys; Sightline surveys; Environmental Surveys.  |   |                         | 2 |   |   |   |   |   |   |         |             | electronics, police, nuclear | x      |        |        |            |  | • [Kirwan & Ainsworth, 1992]   |                          |
| 453. | Interface Testing        | Step   | SwD     | 1992 or older | Interface testing is essentially focused testing. It needs reasonably precise knowledge of the interface specification. It has three aspects: 1) Usability testing (to discover problems that users have); 2) Correctness testing (to test whether the product does what it is supposed to do); 3) Portability testing (to make a program run across platforms).  | Software design & development phase. See also HSIA. See also Software Testing. | 454. | INTEROPS (INTEgrated Reactor OPerator System) | FTS    | HFA<br>,<br>HRA<br>,<br>Task | 1991          | Cognitive performance simulation, which uses the SAINT simulation methodology. Has three independent models: a nuclear power plant model; a network model of operator tasks; and a knowledge base, the operator model being distributed between the latter two. The model is a single operator model. It diagnoses by observance of plant parameters, and subsequent hypothesis generation and testing of the hypothesis. The approach uses Markovian modelling to allow opportunistic monitoring of plant parameters. The model also simulates various errors and PSF (Performance Shaping Factor). Cognitive workload is also modelled, in terms of the contemporary information processing theory of concurrent task management. Also, INTEROPS can utilise a confusion matrix approach to make diagnostic choices.   | The INTEROPS model allows the following to be simulated: forgetting, tunnel-vision; confirmation bias; and mistakes. See also SAINT. |                         | 2 |   | 4 | 5 |   |   |   |   |             | nuclear |        |        | x      |            |   |  | <ul style="list-style-type: none"> <li>• [Kirwan, Part 1, 1998]</li> <li>• [Kirwan, 1995]</li> </ul> |
| 455. | Interview                                     | Gen    | Dat                          | 1950 or older | <p>Method of asking participants what they think about a topic in question, including follow-up questions for clarification. Interviews can be held in different ways:</p> <ul style="list-style-type: none"> <li>• Unstructured Interviews: Very open interviews. Usually an outline, used as a guide, with a limited set of broad questions.</li> <li>• Semi-Structured Interviews: A more structured set of open-ended questions is designed before the interview is conducted. Follow up questions are used for clarification.</li> <li>• Stratified Semistructured Interviews: Representative subgroups of an organisation are identified and randomly sampled individuals are interviewed for each subgroup. This aims to reduce the sampling error.</li> <li>• Structured Interviews: The interviewer has a standard set of questions that are asked of all candidates. Is more commonly used for systematic collection of information.</li> <li>• Exit Interview: Open-ended questions asked after a study or experiment. Purpose is to gather information about the perceived effectiveness of study.</li> <li>• Laddering is used to draw out the connections users make between different constructs of a task, their consequences, and the human values linked with those consequences. The researcher begins with a statement and then directs the expert through the task hierarchy.</li> <li>• Teachback is a process in which the subject matter expert (SME) describes a concept to the researcher. The researcher then explains the concept back to the SME until the SME is satisfied that the researcher has grasped the concept.</li> </ul> | Interviews yield rich qualitative data and can be performed over the telephone or in person.   | 1                       | 2 | 3 | 4 | 5 | 6 | 7 | 8 | ATM, rail, road, manufacturing, healthcare, environment, social | x           | x       | x      | x      | x      | x          | <ul style="list-style-type: none"> <li>• [FAA HFW]</li> <li>• [Hendrick, 1997]</li> <li>• [Kirwan &amp; Ainsworth, 1992]</li> <li>• [Salvendy, 1997]</li> </ul> |  |  |

| 456. | Invariant Assertions                                | Step   | SwD     | 1967 or older | Aim is to detect whether a computer system has deviated from its intended function. An invariant assertion of an automaton A is defined as any property that is true in every single reachable state of A. Invariants are typically proved by induction on the number of steps in an execution leading to the state in question. While proving an inductive step, only critical actions are considered, which affect the state variables appearing in the invariant.   | To be used on non-time critical safety related systems. Related to formal specification methods and fault containment techniques. See also Software Testing. |                         |   |   |   |   |   |   |   |         |             |        |        |        |        |            |  |  | <ul style="list-style-type: none"> <li>• [Bishop, 1990]</li> <li>• [Keidar &amp; Khazan, 2000]</li> </ul>   |
| 457. | IO (Investigation Organizer)                        | Min    | Dat     | 2002          | IO is a web-based information-sharing tool used to support mishap investigations in real-time as well as providing an analysis capability to optimise the investigation activities, report generation, and generic mishap investigation research. The tool functions as a document/data/image repository, a project database, and an “organisational memory” system. Investigation Organizer permits relationships between data to be explicitly identified and tracked using a cross-linkage mechanism, which enables rapid access to interrelated information. The tool supports multiple accident models to help give investigators multiple perspectives into an incident.   | Uses Fault Trees. Developed at NASA Ames Research Center in 2002.  |                         |   |   |   |   |   |   |   |         |             |        |        |        |        |            |  |  | <ul style="list-style-type: none"> <li>• [GAIN AFSA, 2003]</li> <li>• [IO example]</li> </ul>   |
| 458. | IPME (Integrated Performance Modelling Environment) | FTS    | HFA     | 1997 or older | IPME is a Unix-based integrated environment of simulation and modelling tools for answering questions about systems that rely on human performance to succeed. IPME provides: 1) A realistic representation of humans in complex environments; 2) Interoperability with other models and external simulations; 3) Enhanced usability through a user friendly graphical user interface. IPME provides i) a full-featured discrete event simulation environment built on the Micro Saint modelling software; ii) added functionality to enhance the modelling of the human component of the system; iii) a number of features that make it easier to integrate IPME models with other simulations on a real-time basis including TCP/IP sockets and, in the near future, tools for developing simulations that adhere to the Higher Level Architecture (HLA) simulation protocols that are becoming standard throughout the world. | Relation with Micro-SAINT. See also HPM.   |                         |   | 2 |   | 4 | 5 |   |   |         |             |        |        |        |        |            |  |  | <ul style="list-style-type: none"> <li>• [IPME web]</li> <li>• [Dahn &amp; Laughery, 1997]</li> <li>• [Winkler, 2003]</li> <li>• [FAA HFW]</li> <li>• [Alley, 2005]</li> </ul>  |
| 459. | IPS (Interacting Particle System)                   | Math   | Mod     | 2005          | The aim of using this technique within safety analysis is to speed up Monte Carlo simulations that are used to determine the frequency of occurrence of rare events. The technique makes use of repeated sampling of ‘particles’ in Monte Carlo simulations. Particles that do not appear to reach a first area of interest are ‘killed’, after which the Monte Carlo simulation continues with the remaining particles until the next area of interest, and so on. The areas of interest ultimately zoom in to the rare event.  | An example rare event evaluated using this technique is collision between two aircraft. Application of IPS to aviation has been developed as part of TOPAZ.  |                         |   |   |   | 4 |   |   |   |         |             |        |        |        |        |            |  |  | <ul style="list-style-type: none"> <li>• [Cerou et al, 2002]</li> <li>• [Cerou et al, 2006]</li> <li>• [Blom &amp; Krystul &amp; Bakker, 2006]</li> <li>• [Blom &amp; Krystul et al, 2007]</li> <li>• [Blom &amp; Bakker &amp; Krystul, 2007]</li> <li>• [Blom &amp; Bakker &amp; Krystul, 2009]</li> </ul> |

| 460. | IRP<br>(Integrated Risk Picture)             | Int    | OpR     | 2006 | Intends to provide an integrated risk picture for the current and an adopted (2015) ATM concept using fault tree analysis [IRP, 2006]. Starting point is a fault tree for the current situation (see next column of this table). The predictive IRP for the adopted 2015 ATM concept uses a 4-stage approach: Stage 1: Identify the future ATM situation, i.e. identify the ATM changes that might be implemented in Europe the period up to 2020. Use HAZOPs and ongoing safety assessments for the different future ATM components to identify which aspects will positively influence safety, and which aspects will negatively influence safety (hazards). Stage 2: Make a functional model including the main actors, the information flow between them, and interdependencies, for the future situation, using SADT (Structured Analysis and Design Technique). Stage 3: Use this and the current risk fault tree to evaluate the future situation. Stage 4: Refine and quantify the future IRP by assessing correlated modification factors for the values in the IRP fault tree and the IRP influence model, thus modelling positive interactions, negative interactions, and migration of risk. | The current risk IRP [IRP, 2005] accumulates overall risk from five kinds of accident risk categories (CFIT, Taxiway collision, Mid-air collision, Runway collision, Wake turbulence). For each category there is a fault tree that represents the specific causal factors. And below each fault tree there is an influence model which is used to represent more diffuse factors such as quality of safety management, human performance, etc. Quantification is done by mixture of historical data and expert judgement. An adaptation of IRP for use in the SESAR (Single European Sky ATM research) programme is referred to as AIM (Accident Incident Model). |                         | 2 | 3 | 4 | 5 |   |   |   | 8   | ATM         | x      |        | x      |        |  |  | <ul style="list-style-type: none"> <li>• [IRP, 2005]</li> <li>• [IRP, 2006]</li> </ul> |
| 461. | ISA<br>(Intelligent Safety Assistant)        | Dat    | Dat     | 1987 | ISA is intended to facilitate the interactive collection of data on accidents and near misses. It is a method of applying MORT methods for registration of incidents at work in order to ensure consistent data collection and the generation of diagnostic messages about critical or failing safety management factors underlying a single accident, near miss or Safety Management System (SMS) failure event.  | ISA is claimed to contribute to consistency in reporting accidents and incidents, and to the development of causal hypotheses. Developed by Koorneef and Hale (Delft University of Technology, Netherlands).   |                         |   |   |   |   |   |   | 8 | healthcare, chemical, oil&gas, mining,aircraft, manufacturing | x           |        | x      | x      | x      | <ul style="list-style-type: none"> <li>• [HEAT overview]</li> <li>• [Livingston, 2001]</li> <li>• [Korneef, 2000]</li> </ul> |  |  |
| 462. | ISAM<br>(Integrated Safety Assessment Model) | Stat   | OpR     | 2012 | The objective of ISAM is to estimate the risk of the U.S. National Airspace System (NAS), in the baseline situation and specifically after introduction of NextGen Operational Improvements (OIs). The core of ISAM is a causal risk model consisting of 30 accident scenarios that are represented as Event Sequence Diagrams and associated Fault Trees. The model provides an estimate of the baseline risk of the U.S. NAS, using historic accident and incident information. This risk model is complemented with an ISAM predictive mode, i.e. an influence model and a graphical user interface (GUI) that can be used to solicit expert opinion to provide an estimate of the risk effects of NextGen changes to the NAS.  | The structure of the model is based on the structure of two similar models developed in Europe, i.e. Eurocontrol's Integrated Risk Picture (IRP) and the Dutch Causal Model for Air Transport Safety (CATS), modified to appropriately represent accident and incident scenarios in the U.S. The ISAM model is currently still being developed.  |                         |   | 3 | 4 | 5 |   |   |   | (aviation), (ATM), (airport)                                  | x           |        | x      |        | x      | <ul style="list-style-type: none"> <li>• [ISAM, 2011]</li> <li>• [Borener et al, 2012]</li> </ul>                            |  |  |

| 467. | JHEDI (Justification of Human Error Data Information) | Step   | HRA , Task | 1989          | JHEDI is derived from the Human Reliability Management System (HRMS) and is a quick form of human reliability analysis that requires little training to apply. The tool consists of a scenario description, task analysis, human error identification, a quantification process, and performance shaping factors and assumptions. JHEDI is a moderate, flexible and auditable tool for use in human reliability analysis. Some expert knowledge of the system under scrutiny is required.   | Developed by Kirwan et al. See also HRMS.   |                         |   |   |   |   |   |   |   |         |             |        |        |        |        |            |  |  | <ul style="list-style-type: none"> <li>• [HIFA Data]</li> <li>• [Kirwan, 1994]</li> <li>• [Kirwan, Part 1, 1998]</li> <li>• [PROMA15, 2001]</li> </ul> |
|      | Job Process Chart                                     |        |            |               |   | See OSD (Operational Sequence Diagram)  |                         |   |   |   |   |   |   |   |         |             |        |        |        |        |            |  |  |  |
| 468. | Job Safety Analysis                                   | Step   | Task       | 1960 about    | This technique is used to assess the various ways a task may be performed so that the most efficient and appropriate way to do a task is selected. Each job is broken down into tasks, or steps, and hazards associated with each task or step are identified. Controls are then defined to decrease the risk associated with the particular hazards. Steps are: 1) Inventory occupations; 2. Inventory tasks within occupations; 3. Identify critical tasks; 4. Analyse critical tasks; 5. Write procedures and practices; 6. Put to work; 7. Update and maintain records.   | Job Safety Analysis can be applied to evaluate any job, task, human function, or operation. A critical task is a task which has the potential to produce major loss to people, property, process and/or environment when not performed properly. Also referred to as Job Hazard Analysis (JHA) or Task Hazard Analysis. |                         |   | 2 | 3 |   |   |   | 6 |         |             |        |        |        |        |            |  |  | <ul style="list-style-type: none"> <li>• [FAA00]</li> <li>• [ΣΣ93, ΣΣ97]</li> <li>• [FAA HFW]</li> <li>• [Gallant, 2001]</li> </ul>                    |

| 469. | Journalled Sessions                                   | Tab    | SwD        | 1993 or older | A journalled session is a way to evaluate the usability of software remotely. Users are provided with a disk or CD containing the prototype interface and are asked to perform a variety of tasks. The software itself captures information relative to the users' actions (keystrokes, mouseclicks). The software usually has dialog boxes that allow the user to input comments as well. Upon completion of the tasks the software is then returned for subsequent evaluation.  | See also Self-Reporting Logs  |                         |   |   |   |   |   |   | 5 |         |             |        |        |        |        |            |  |  | <ul style="list-style-type: none"> <li>• [Nielsen, 1993]</li> <li>• [FAA HFW]</li> </ul>   |
| 470. | JSD (Jackson System Development)                      | Int    | Des        | 1982          | JSD is a system development method for developing information systems with a strong time dimension from requirements through code. JSD simulates events dynamically as they occur in the real world. Systems developed using JSD are always real-time systems. JSD is an object-based system of development, where the behaviour of objects is captured in an entity structure diagram. It consists of three main phases: the modelling phase; the network phase; and the implementation phase. JSD uses two types of diagrams to model a system, these are Entity Structure Diagrams and Network Diagrams. When used to describe the actions of a system or of an entity, JSD Diagrams can provide a modelling viewpoint that has elements of both functional and behavioural viewpoints. JSD diagrams provide an abstract form of sequencing description, for example much more abstract than pseudocode. | Developed by Michael A. Jackson and John Cameron. Considered for real-time systems where concurrency can be allowed and where great formality is not called for. Similarities with MASCOT. Tools available. Software requirements specification phase and design & development phase.                                   |                         |   | 2 |   |   |   |   |   |         |             |        |        |        |        |            |  |  | <ul style="list-style-type: none"> <li>• [Bishop, 1990]</li> <li>• [EN 50128, 1996]</li> <li>• [Rakowsky]</li> </ul>                                   |

| 471. | KAOS<br>(Knowledge Acquisition in autOmedated Specification)                     | Stat   | Des     | 1990 | KAOS is a goal-oriented software requirements capturing approach which consists of a formal framework based on temporal logic and AI (artificial intelligence) refinement techniques where all terms such as goal and state are consistently and rigorously defined. The main emphasis of KAOS is on the formal proof that the requirements match the goals that were defined for the envisioned system. KAOS defines a goal taxonomy having 2 dimensions: Goal patterns (Achieve, Cease, Maintain, Avoid, Optimize.); Goal categories. Goal categories form a hierarchy. At the root of the hierarchy are system goals and private goals. System goals have the following sub-categories: Satisfaction goal, information goal, robustness goal, consistency goal, safety and privacy goal.  | Designed by the University of Oregon and the University of Louvain (Belgium). Alternatively, KAOS stands for Keep All Objects Satisfied. See also i*. | 472. | KLM<br>(Keystroke Level Model)<br>or<br>KLM-GOMS<br>(Keystroke-Level Model GOMS) | Stat   | Task    | 1983 | KLM is an 11-step method that can be used to estimate the time it takes to complete simple data input tasks using a computer and mouse. It can be used to find more efficient or better ways to complete a task, by analyzing the steps required in the process and rearranging or eliminating unneeded steps. A calculation of the execution time for a task can be made by defining the operators that will be involved in a task, assigning time values to those operators, and summing up the times. Different systems can be compared based on this time difference. Uses: Obtain time predictions to compare systems of predict improvements. Input: Observable behaviour such as button pushes and mouse movements. Components: Six operators: K – keystroke or mouse movement; P – pointing to a target; D – moving the mouse to draw line segments; H – moving hands from mouse to keyboard; M – mental preparation; R – system response time | KLM is a simplified version of GOMS in that it focuses on very low level tasks. It is usually applied in situations that require minimal amounts of work and interaction with a computer interface or software design. See also CAT, CPM-GOMS, CTA, GOMS, GOMS, NGOMSL. |                         | 2 |   |   |   |   |   | 7 |         | electronics, space         |  |        | x      |        |            | <ul style="list-style-type: none"> <li>• [FAA HFW]</li> <li>• [Eberts, 1997]</li> <li>• [Hochstein, 2002]</li> <li>• [Card, 1983]</li> <li>• [John &amp; Kieras, 1996]</li> </ul> |   |
| 473. | KTT<br>(Kinetic Tree Theory)   | Stat   | Par     | 1969 | Mathematical technique used to quantify top effect of fault trees, allowing for evaluation of instantaneous reliability or availability. Complete information is obtained from the existence probability, the failure rate, and the failure intensity of any failure (top, mode or primary) in a fault tree. When these three characteristics are determined, subsequent probabilistic information, both pointwise and cumulative, is obtained for all time for this failure. The application of the addition and multiplication laws of probability are used to evaluate the system unavailability from the minimal cut sets of the system.   | Developed by W.E. Vesely (Idaho Nuclear Corporation) in 1969. Supported by computer program named KITT. Used for FTA.   |                         |   |   |   |   | 5 |   |   |         | nuclear, chemical, oil&gas | x  |        |        |        |            | <ul style="list-style-type: none"> <li>• [MUFTIS3.2-I, 1996]</li> <li>• [Vesely, 1970]</li> </ul>   |   |

| 474. | Laser Safety Analysis                               | Step   | HzA     | 1960 | This analysis enables the evaluation of the use of Lasers from a safety view. The purpose is to provide a means to assess the hazards of non-ionising radiation. As such, its intent is also to identify associated hazards and the types of controls available and required for laser hazards. Lasers are usually labeled with a safety class number, which identifies how dangerous the laser is, ranging from 'inherently safe' to 'can burn skin'.  | Laser = Light Amplification by Stimulated Emission of Radiation. Theoretic foundations for the laser were established by Albert Einstein in 1917. The term LASER was coined by Gordon Gould in 1958. The first functional laser was constructed in 1960 by Theodore H. Maiman. Laser Safety Analysis is appropriate for any laser operation, i.e. construction, experimentation, and testing. |                         |   | 3 |   |   |   |   | 6 |         |             |        |        | healthcare, defence  | x      |            |  |  |   | <ul style="list-style-type: none"> <li>[FAA AC431]</li> <li>[FAA00]</li> <li>[ΣΣ93, ΣΣ97]</li> </ul> |
| 475. | Library of Trusted, Verified Modules and Components | Dat    | Des     |      | Well designed and structured PESs (Programmable Electronic Systems) are made up of a number of hardware and software components and modules which are clearly distinct and which interact with each other in clearly defined ways. Aim is to avoid the need for software modules and hardware component designs to be extensively revalidated or redesigned for each new application. Also to advantage designs which have not been formally or rigorously validated but for which considerable operational history is available. | Software design & development phase.  |                         |   |   |   |   |   |   |   |         |             |        | 8      | software, (rail)   |        | x          |  |  | <ul style="list-style-type: none"> <li>[EN 50128, 1996]</li> <li>[Rakowsky]</li> </ul>  |  |

| 478. | LISA<br>(Low-level<br>Interaction Safety<br>Analysis) | Step   | HzA     | 1999<br>or<br>older | LISA was developed to study the way in which an operating system manages system resources, both in normal operation and in the presence of hardware failures. Instead of analysing the system functionality, LISA focuses on the interactions between the software and the hardware on which it runs. A set of physical resources and timing events is identified, and a set of projected failure modes of these resources is considered. The aim of the analysis is to use a combination of inductive and deductive steps to produce arguments of acceptability demonstrating either that no plausible cause can be found for a projected failure, or that its consequences would always lead to an acceptable system state. Step 1: Agree principles for acceptability; Step 2: Assemble source material; Step 3: Analyse timing events; Step 4: Analyse physical resources. | Developed by University of York. | 479. | Littlewood  | Math   | SwD     | 1957                | Mathematical model that tends to provide the current failure rate of a program, and hence minimum time required to reach a certain reliability.  | Not considered very reliable, but can be used for general opinion and for comparison of software modules. |                         |   |   |   |   | 5 |   |   |         |             | (software) |                        | x      |        |            |  | • [Bishop, 1990]                       |                   |
| 480. | Littlewood-Verrall                                    | Math   | SwD     | 1957                | A Bayesian approach to software reliability measurement. Software reliability is viewed as a measure of strength of belief that a program will operate successfully. The value of the hazard rate is modelled as a random variable. One of the parameters of the distribution of this random variable is assumed to vary with the number of failures experienced. The value of the parameters of each functional form that produce the best fit for that form are determined. Then the functional forms are compared (at the optimum values of the parameters) and the best fitting form is selected.  | Not considered very reliable, but can be used for general opinion and for comparison of software modules. |                         |   |   |   |   | 5 |   |   |         |             | (software) |                        | x      |        |            |  | • [Bishop, 1990]<br>• [Narkhede, 2002] |                   |

| 481. | Logic Diagram                               | Gen    | Mod     | 300<br>or<br>1761 | A Logic Diagram is intended to provide structure and detail as a primary hazard identification procedure. Its graphic structure is a means of capturing and correlating the hazard data produced by the other tools. Because of its graphic display, it can also be a hazard-briefing tool. There are three types of Logic Diagrams. (1) The Positive diagram is designed to highlight the factors that must be in place if risk is to be effectively controlled in the operation. It works from a safe outcome back to the factors that must be in place to produce it. (2) The Event diagram focuses on an individual operational event (often a failure or hazard identified using the "What If" tool) and examines the possible consequences of the event. It works from an event that may produce risk and shows what the loss outcomes of the event may be. (3) The Negative diagram selects a loss event and then analyzes the various hazards that could combine to produce that loss. It works from an actual or possible loss and identifies what factors could produce it. | Closely related techniques are FTA, ETA, RBD. Many other examples of Logic Diagrams have been described, such as Begriffsschrift, Binary decision diagrams, Concept maps, Implication diagrams, Kripke models, Venn diagrams, Euler diagrams, Existential graphs, Spider diagrams, Carroll diagrams, Karnaugh maps, Operation tables, Truth tables, Argument maps, Porphyrian trees, and Semantic tableaux. Some of these formalisms are quite old, e.g. Begriffsschrift dates from 1879. Venn diagrams date from 1880. Euler diagrams date from 1712. Porphyrian trees date from about the 3rd century AD. According to [MacQueen, 1967], the modern Logic Diagram dates from 1761. |                         |   |   |   | 4 |   |   |   |         |             |                            | all | x |   |            |  |  |   | <ul style="list-style-type: none"> <li>[FAA00]</li> <li>[MacQueen, 1967]</li> </ul> |

| 482. | LOPA<br>(Layer of Protection Analysis)      | Tab    | Mit     | 2001              | A tabular representation of both the risk factors and the risk mitigating factors is used to determine a safety integrity level (SIL). LOPA starts by quantifying the consequences and likelihood of a hazardous event in the absence of any forms of protection or risk mitigation measures: the underlying process risk is defined. Potential risk reduction measures are then systematically analysed and their impact on the process risk is quantified to determine a mitigated risk. The mitigated risk is compared with risk targets, which then determines a risk reduction factor to be provided. The risk reduction factor translates directly into a SIL. A detailed LOPA procedure is required to define categories for hazardous event consequences, and guideline risk reduction factors for typical protection layers. Calibration of the LOPA procedure is needed to ensure that defined risk acceptability criteria are met.   | Developed by the American Institute of Chemical Engineers Centre for Chemical Process Safety (CCPS) in response to the requirements of ISA S84.01 and was formally published in 2001 under the title 'Layer of Protection Analysis, Simplified Process Risk Assessment'. Reference [ACM, 2006] lists some advantages and disadvantages.  |                         |   |   |   |   |   | 5 | 6 |         |             | chemical, nuclear, oil&gas | x   |   |   |            |  |  | <ul style="list-style-type: none"> <li>[Gulland, 2004]</li> <li>[ACM, 2006]</li> <li>[Summers, 2002]</li> </ul> |   |
| 483. | LOS<br>(Level of Safety)                    | Math   | Col     | 2000              | Assessment of a Level of Safety for a dedicated block of airspace expressed as probability to encounter aircraft conflicts. LOS is a tool to quantify the potential hazards for persons or goods involved in aviation. Traffic behaviour, traffic level and infrastructure layout form individual scenarios for which a LOS figure can be computed. Intended to support procedure design and allow to increase the stakeholder's situational awareness to bottlenecks and to judge new concepts.  | Current investigations focus on the TMA (Terminal Manoeuvring Area).   |                         |   |   |   | 4 | 5 |   |   |         |             | (ATM)                      | x   |   | x |            |  |  | <ul style="list-style-type: none"> <li>[GfL web]</li> <li>[GfL, 2001]</li> <li>[TUD, 2005]</li> </ul>           |   |

| 487. | MA-DRM (Multi-Agent Dynamic Risk Modelling)                          | Dyn, Int | Mod, OpR | 2003 | MA-DRM uses scenario-based Monte Carlo simulations and uncertainty evaluations to analyse the safety risk of future or current air traffic operations. It includes the development of a Multi-Agent stochastic dynamic risk model of the air traffic scenario, which defines the stochastic dynamics of agents (human operators and technical systems) in the air traffic scenario considered, as well as their dynamic interactions. Here, the dynamics and interactions include deterministic and stochastic relationships, as is appropriate for the human performance or system considered. The methodology incorporates a risk bias and uncertainty assessment, including sensitivity analysis, which gives insight into the extent to which the various agents contribute to both safety and safety risk. | MA-DRM was developed as part of the TOPAZ methodology, where typically, the stochastic dynamic model is formulated as an SDCPN (Stochastically and Dynamically Petri Net). |                         |   |   |   |   |   |   |   |         |             |        |        |        |        |            |  |  | <ul style="list-style-type: none"> <li>• [Blom &amp; Stroeve &amp; DeJong, 2006]</li> <li>• [Stroeve et al, 2011]</li> <li>• [Everdij et al, 2006]</li> <li>• [Stroeve et al, 2003]</li> <li>• [Stroeve et al, 2013]</li> </ul> |  |
| 488. | MAIM (Merseyside Accident Information Model)                         | Dat, Tab | Ret      | 1987 | MAIM is a method of recording information on accidents, in order to trace an accident back to the first unforeseen event. It attempts to capture all relevant information in a structured form so that sets of similar accidents can be compared to reveal common causes. The concept is to identify the first unexpected event, perceived by the injured person, and to trace all subsequent events which lead to injury. Events are short sentences which can produce a brief report. MAIM records event verbs and objects in the environment. In addition, it records personal information and other components which may be relevant to the accidents. MAIM can be represented in a diagram.  | Developed by Derek Manning, an occupational physician. Focused on studying injuries due to e.g. occupational or household events.  |                         |   |   |   |   |   |   |   |         |             |        |        |        |        |            |  |  | <ul style="list-style-type: none"> <li>• [Kjellen, 2000]</li> <li>• [Liverpool, 2004]</li> <li>• [MAIM web]</li> <li>• [Davies &amp; Shannon, 2011]</li> </ul>  |  |
| 489. | MANAGER (MANagement Assessment Guidelines in the Evaluation of Risk) | Tab      | Org      | 1990 | Aims to assess the performance of the safety management system and provides recommendations for improvement. MANAGER is an auditing-based method, in which questionnaires are used to evaluate performance indicators associated with specific plant departments, such as operations and maintenance. Indices associated with the "quality" of these departments then are developed to provide a score relative to industry norms. The tool consists of approximately 114 questions, divided into 12 areas such as Written procedures, Safety policy, Formal safety studies, Organisational factors, etc.   | MANAGER was the first technique to consider linking up ratings on its audit questions with PSA results.  |                         |   |   |   |   |   |   |   |         |             |        |        |        |        |            |  |  |   | <ul style="list-style-type: none"> <li>• [Kennedy &amp; Kirwan, 1998]</li> <li>• [Kirwan, 1994]</li> </ul> |

| 490. | MAPPS (Maintenance Personnel Performance Simulations) | FTS    | HFA , Task | 1984 | Computer-based, stochastic, task-oriented model of human performance. It is a tool for analysing maintenance activities in nuclear power plants, including the influence from environmental, motivational, task and organisational variables. Its function is to simulate a number of human 'components' to the system, e.g. the maintenance mechanic, the instrument and control technician together with any interactions (communications, instructions) between these people and the control-room operator.   |   |                         |   |   | 4 | 5 |   |   |   |         |             | (nuclear)   |        |        | x      | x          | x | <ul style="list-style-type: none"> <li>• [Kirwan, 1994]</li> <li>• [MIL-HDBK, 1999]</li> <li>• [THEMES, 2001]</li> </ul>   |
| 491. | Markov Chains or Markov Modelling                     | Math   | Mod        | 1906 | Equal to SSG where the transitions to the next stage only depend on the present state. Only for this type of SSG, quantification is possible. Can be used to evaluate the reliability or safety or availability of a system.   | Named after Russian mathematician A.A. Markov (1856-1922). Standard model for dependability evaluation of redundant hardware. Also used for decision making. Combines with FMEA, FTA, CDM or CCA. Tools available.  |                         |   |   | 4 | 5 |   |   |   |         |             | manufacturing, chemical, finance, management, energy, environment, aircraft | x      | x      |        |            |   | <ul style="list-style-type: none"> <li>• [Bishop, 1990]</li> <li>• [EN 50128, 1996]</li> <li>• [FT handbook, 2002]</li> <li>• [MUFTIS3.2-I, 1996]</li> <li>• [NASA-GB-1740.13-96]</li> <li>• [Rakowsky]</li> <li>• [Sparkman, 1992]</li> <li>• [Storey, 1996]</li> </ul> |
| 492. | Markov Latent Effects Tool                            | Math   | Org        | 1999 | The Markov Latent Effects Tool aims at the quantification of safety effects of organisational and operational factors that can be measured through "inspection" or surveillance. The tool uses a mathematical model for assessing the effects of organisational and operational factors on safety. For example, organisational system operation might depend on factors such as accident/incident statistics, maintenance personnel/operator competence and experience, scheduling pressures, and safety culture of the organisation. Because many of the potential metrics on such individual parameters could be difficult (and generally uncertain) to determine, the method includes guidance for this. Also, there may be ill-defined interrelations among the contributors, and this is also addressed through "dependence" metrics. | Markov Latent Effects Model is based on a concept wherein the causes for inadvertent operational actions are traced back through latent effects to the possible reasons undesirable events may have occurred. The Markov Latent Effects Model differs substantially from Markov processes, where events do not depend explicitly on past history, and Markov chains of arbitrary order, where dependence on past history is completely probabilistic. |                         |   |   |   | 5 |   |   |   |         |             | aviation, aircraft  |        |        |        | x          | x | <ul style="list-style-type: none"> <li>• [GAIN AFSA, 2003]</li> <li>• [Cooper, 2001]</li> <li>• [FAA HFW]</li> </ul>   |
| 493. | MARS (Major Accident Reporting System)                | Dat    | Dat. Ret   | 1984 | MARS was established to gather information regarding 'major accidents' and other events with 'unusual characteristics' in the nuclear processing domain.   | Established by EU.  |                         |   |   |   |   |   |   |   | 8       |             | nuclear, oil&gas, chemical  | x      | x      | x      | x          | x | <ul style="list-style-type: none"> <li>• [Salmon et al., 2005]</li> </ul>  |

| 494. | MASA Propagation Model (Multi-Agent Situation Awareness Propagation Model) | Gen    | Mod     | 2001 about    | The Situation Awareness of an operator may be erroneous for several reasons, e.g., wrong perception of relevant information, wrong interpretation of perceived information, wrong prediction of a future state and propagation of error due to agent communication. A situation awareness error can evolve and expand as it is picked up by other humans or agents ('Chinese whispering'). This error propagation between multiple agents can be modelled and analysed using e.g. stochastic hybrid models.   | Chinese whispering is a game in which the first player whispers a phrase or sentence to the next player. Each player successively whispers what that player believes he or she heard to the next. The last player announces the statement to the entire group. Errors typically accumulate in the retellings, so the statement announced by the last player differs significantly, and often amusingly, from the one uttered by the first. |                         |   |   |   | 4 |   |   |   |         |             |    |    |    |    |            |  | <ul style="list-style-type: none"> <li>[DiBenedetto et al, 2005]</li> <li>[Stroeve &amp; Blom &amp; Park, 2003]</li> <li>[Stroeve et al, 2012]</li> <li>[Blom &amp; Stroeve, 2004]</li> </ul> |
| 495. | MASCOT (Modular Approach to Software Construction, Operation and Test)     | Stat   | Des     | 1975          | A method for software design aimed at real-time embedded systems from the Royal Signals and Research Establishment, UK. It is not a full method in the current sense of design methodology. It has a notation and a clear mapping between the design and physical components. MASCOT III copes better with large systems than did earlier versions, through better support for the use of sub-systems.  | MASCOT originated within the UK defence industry in the 1970s. The MASCOT III standard was published in its final form in 1987. Considered for real-time systems where concurrency has to and can be used. Related to JSD. Tools available. Software requirements specification phase and design & development phase.  |                         | 2 |   |   |   |   | 6 |   |         |             |    |    | x  |    |            |  | <ul style="list-style-type: none"> <li>[Bishop, 1990]</li> <li>[EN 50128, 1996]</li> <li>[MASCOT handbook]</li> <li>[Rakowsky]</li> </ul>   |
| 496. | Materials Compatibility Analysis   | Step   | HZA     | 1988 or older | Materials Compatibility Analysis provides an assessment of materials utilised within a particular design. Any potential physical degradation that can occur due to material incompatibility is evaluated on potential contributory hazards or failures that can cause mishaps to occur. Material compatibility is critical to the safe operation of a system and personnel safety. The result of a material misapplication can be catastrophic.   | Materials Compatibility Analysis is appropriate throughout most systems. Proper material compatibility analysis requires knowledge of the type, concentration and temperature of fluid(s) being handled and the valve body and seal material.  |                         |   | 3 |   | 5 |   |   |   |         |             |    |    | x  |    |            |  | <ul style="list-style-type: none"> <li>[FAA AC431]</li> <li>[FAA00]</li> <li>[ΣΣ93, ΣΣ97]</li> </ul>  |
| 497. | MBSA (Model Based Safety Analysis)   | Int    | HZA     | 2005          | MBSA is an approach in which the system and safety engineers share a common system model. The system design process captures, using a modelling language, the architecture and functional behaviour of the system under normal operating conditions (nominal model behaviour). The safety process augments the nominal model with failure mode models, failure condition formulae, and common cause events. The resulting model is called the Failure Propagation Model (FPM). The analyst applies a software application to perform an analysis of the system FPM and generate outputs such as failure sequences, minimal cutsets, or other results. These fault simulation scenario outputs are evaluated by safety engineers as part of the overall safety assessment process. | Developed as part of ARP4761A. The MBSA methodology may vary due to the type and capability of the system modelling languages, the extent to which nominal behaviour is captured, and the range of output results. These variants allow the methodology to be adapted to different scopes of analysis and varying complexity/ detail of the systems being modelled. Techniques that may be used are FTA, CCA, FMEA.                        |                         |   | 3 | 4 | 5 | 6 |   |   |         |             |    |    | x  | x  |            |  | <ul style="list-style-type: none"> <li>[Joshi et al, 2006]</li> </ul>   |

| 498. | MCA Analysis (Maximum Credible Accident Analysis) or WCA (Worst Case Analysis)         | Step      | OpR, Mit | 1972 or older | This technique aims to determine the scenarios with the worst possible outcome but that are still credible, and to develop strategies to mitigate the consequences of these accidents. MCA analysis does not include quantification of the probability of occurrence of an accident. In practice, the selection of accident scenarios for MCA analysis is carried out on the basis of engineering judgement and past accident analysis.  | Similar to Scenario Analysis, this technique is used to conduct a System Hazard Analysis.  |                         |   |   |   | 4 |   | 6 |   |         |             |   | oil&gas, nuclear, chemical, environment, (aircraft), (aviation) | x      |        |            |   |   |  | <ul style="list-style-type: none"> <li>• [FAA00]</li> <li>• [ΣΣ93, ΣΣ97]</li> <li>• [Oil India]</li> </ul> |
|      | MCDA (Multi-Criteria Decision Analysis)  |           |          |               |  | See MCDM (Multiple Criteria Decision Making)   |                         |   |   |   |   |   |   |   |         |             |   |   |        |        |            |   |   |  |  |
| 499. | MCDET (Monte Carlo Dynamic Event Tree)   | FTS       | Mod      | 2006          | MCDET couples DDET with discrete event Monte Carlo (MC) Simulation to investigate in a more efficient way (by acceleration of simulation) the whole tree of events. Discrete-valued variables are treated by DDET, whereas continuous-valued variables are handled by discrete event MC simulation. For each set of values provided by the discrete event MC simulation, MCDET generates a new DDET.   | Developed by Gesellschaft für Anlagen- und Reaktorsicherheit (GRS).  |                         |   |   |   |   |   | 5 |   |         |             | nuclear   | x   |        |        |            |   |   | <ul style="list-style-type: none"> <li>• [Kloos &amp; Peschke, 2006]</li> <li>• [Hofer et al, 2001]</li> </ul> |  |
| 500. | MCDM (Multiple Criteria Decision Making) or MCDA (Multiple Criteria Decision Analysis) | Gen, Math | Dec      | 1960          | MCDM is a sub-discipline of operations research that explicitly considers multiple criteria (e.g. cost, quality, safety, efficiency) in decision-making environments. It can be used to identify and model key factors to rank/evaluate scenarios about safety risk. Typically, there does not exist a unique optimal solution and it is necessary to use decision maker's preferences to differentiate between solutions. Normally one has to "tradeoff" certain criteria for others. A major distinction between MCDM problems is based on whether the solutions are explicitly or implicitly defined. In the latter case, the number of alternatives is usually very large or even infinite.  | Many specific MCDM methods exist; see e.g. AHP. Different methods require different types of raw data and follow different optimization algorithms. Some techniques rank options, some identify a single optimal alternative, some provide an incomplete ranking, and others differentiate between acceptable and unacceptable alternatives. Numerous applications. See also Brown-Gibson model, SLIM. |                         |   |   |   |   |   | 5 |   |         |             | road, finance, manufacturing, management, nuclear, environment, oil&gas, social | x   | x      | x      | x          | x | x | <ul style="list-style-type: none"> <li>• [Linkov et al., 2004]</li> <li>• [Koksalan et al., 2011]</li> </ul>   |  |
| 501. | MDTA (Misdiagnosis Tree Analysis)  | Stat      | OpR      | 2005          | The MDTA process starts with a given scenario defined in terms of an initiating event. To identify diagnosis failures, a misdiagnosis tree is compiled with the procedural decision criteria as headers and the final diagnoses as end states. In connection with each decision criterion presented in the header, the analyst is guided to consider three types of contributors to diagnosis failures. • Plant dynamics: mismatch between the values of the plant parameters and the decision criteria of the diagnostic rule of the emergency operating procedure due to dynamic characteristics. • Operator error: errors during information gathering or rule interpretation. • Instrumentation failure: problems in the information system. | Developed at Korean Atomic Energy Research Institute.  |                         |   |   | 3 | 4 | 5 |   |   |         |             | nuclear   | x   |        | x      |            |   |   | <ul style="list-style-type: none"> <li>• [Kim et al, 2005]</li> <li>• [Reer, 2008]</li> </ul>                  |  |

| 502. | Measurement of Complexity  | Gen    | SwD      | 1981 or older | Software's complexity is evaluated in order to determine if the level of complexity may contribute to areas of concern for workability, understandability, reliability and maintainability. Highly complex data and command structures are difficult, if not impossible, to test thoroughly and can lead to errors in logic either in the initial build or in subsequent updates. Complexity can be measured via McCabe's metrics, Halstead's metrics, or similar techniques. One can also examine critical areas of the detailed design and any preliminary code for areas of deep nesting, large numbers of parameters to be passed, intense and numerous communication paths, etc. Output products are complexity metrics, predicted error estimates, and areas of high complexity identified for further analysis or consideration for simplification. | Complex software may increase the likelihood of errors, is more likely to be unstable, or may suffer from unpredictable behaviour. Modularity is a useful technique to reduce complexity. See also Avoidance of Complexity.          |                         |   |   |   |   |   |   |   |         |             |        |        |        |        |            |  | <ul style="list-style-type: none"> <li>• [FAA00]</li> <li>• [NASA-GB-1740.13-96]</li> <li>• [Rakowsky]</li> </ul>  |
| 503. | MEDA (Maintenance Error Decision Aid)  | Int    | HRA, Mit | 1995          | MEDA is a widely used attempt to systematise evaluation of events, problems and potential problems by using a repeatable, structured evaluation program. It is a structured investigation process used to determine the factors that contribute to errors committed by maintenance technicians and inspectors. MEDA is also used to help develop corrective actions to avoid or reduce the likelihood of similar errors. Most of these corrective actions will be directed towards the airline maintenance system, not the individual technical or inspector. The MEDA process involves five basic steps: Event, Decision, Investigation, Prevention Strategies, and Feedback.   | MEDA was developed by Boeing as part of the Boeing Safety Management System (BSMS). Link to PEAT, REDA and CPIT. HFACS-ME is a Maintenance Extension of HFACS, similar to MEDA, applicable to navy maintenance events.               |                         |   |   |   |   |   |   |   |         |             |        |        |        |        |            |  | <ul style="list-style-type: none"> <li>• [Bongard, 2001]</li> <li>• [Escobar, 2001]</li> <li>• [HIFA Data]</li> <li>• [MEDA]</li> <li>• [FAA HFW]</li> <li>• [MEDA Users Guide]</li> </ul>   |
| 504. | Memorizing Executed Cases  | Step   | Mit      | 1987          | Aim is to force the software to fail-safe if it executes an unlicensed path. During licensing, a record is made of all relevant details of each program execution. During normal operation each program execution is compared with the set of licensed executions. If it differs a safety action is taken.   | Little performance data available. Related to testing and fail-safe design. Software architecture phase. See also Fail Safety. See also Vital Coded Processor. Also referred to as Execution Flow Check. Related to Watchdog Timers. |                         |   |   |   |   |   |   |   |         |             |        |        |        |        |            |  | <ul style="list-style-type: none"> <li>• [Bishop, 1990]</li> <li>• [EN 50128, 1996]</li> <li>• [Rakowsky]</li> </ul>   |
| 505. | MERMOS (Méthode d'Évaluation de la Réalisations des Missions Opérateur pour la Sureté) | Stat   | HRA      | 1998          | MERMOS is a HRA method based on the notion of Human Factor Missions, which refer to a set of macroactions the crew has to carry out in order to maintain or restore safety functions. Four major steps are involved in the MERMOS method. 1) Identify the safety functions that are affected, the possible functional responses, the associated operation objectives, and determine whether specific means are to be used. 2) Break down the safety requirement corresponding to the HF mission. 3) Bridge the gap between theoretical concepts and real data by creating as many failure scenarios as possible. 4) Ensure the consistency of the results and integrate them into PSA event trees.   | Developed by Electricité de France, since early 1998. See also MONACOS.  |                         |   |   |   | 4 |   |   |   |         |             |        |        |        |        |            |  | <ul style="list-style-type: none"> <li>• [HRA Washington, 2001]</li> <li>• [Bieder et al., 1998]</li> <li>• [Jeffcott &amp; Johnson, 2002]</li> <li>• [Straeter et al, 1999]</li> <li>• [THEMES, 2001]</li> <li>• [Wiegman et al, 2000]</li> </ul> |

| 506. | MES<br>(Multilinear Events Sequencing)                                  | Int    | OpR,<br>Ret | 1975                | MES is an integrated system of concepts and procedures to investigate a wide range of occurrences, before or after they happen. It treats incidents as processes, and produces descriptions of the actions and interactions required to produce observed process outcomes. The descriptions are developed as matrix-based event flow charts showing the coupling among the interactions with links where sequential, if-then and necessary and sufficient logic requirements are satisfied. The investigations focus on behaviours of people and objects, demonstrating what they did to influence the course of events, and then defining candidate changes to reduce future risks. | The first version of MES was developed in 1975 by Starline Software. See also STEP.  |                         |   |   |   |   |   |   |   |         | 8           | police,<br>aviation,<br>chemical  | x      |        | x      | x          | x | <ul style="list-style-type: none"> <li>• [GAIN AFSA, 2003]</li> <li>• [MES guide]</li> <li>• [Benner, 1975]</li> <li>• [MES tech]</li> <li>• [FAA HFW]</li> </ul> |

| 508. | MIDAS<br>(Man-Machine Integrated Design and Analysis System)            | Int    | HFA         | 1986                | MIDAS is an integrated suite of software components to aid analysts in applying human factors principles and human performance models to the design of complex human systems; in particular, the conceptual phase of rotorcraft crewstation development and identification of crew training requirements. MIDAS focuses on visualisation, contains different models of workload and situation awareness within its structure and contains an augmented programming language called the Operator Procedure Language (OPL) incorporated into its programming code.   | Developed by Jim Hartzell, Barry Smith and Kevin Corker in 1986, although the original software has been changed since. MIDAS v5 contains a visualization capability associated with the physical and cognitive operations in their respective contexts. Sometimes referred to as NASA MIDAS to distinguish it from its augmented version Air-MIDAS. See also Air-MIDAS. | 1                       | 2 |   | 4 | 5 |   |   |   |         |             | (aircraft),<br>nuclear, space,<br>aviation,<br>police, defence,<br>navy |        |        | x      | x          |   | <ul style="list-style-type: none"> <li>• [HAIL]</li> <li>• [GAIN ATM, 2003]</li> <li>• [Morrison, 2003]</li> <li>• [FAA HFW]</li> <li>• [Gore, 2010]</li> </ul>   |

| 509. | Mission Analysis                    | Int    | OpR, Task | 1971 or older | <p>Is used to define what tasks the total system (hardware, software, and liveware) must perform. The mission or operational requirements are a composite of requirements starting at a general level and progressing to a specific level. Has two components:</p> <ul style="list-style-type: none"> <li>•Mission Profile. Provides a graphic, 2D representation of a mission segment. Represents the events or situations that maintainers or operators could confront in a new system. Mission profiles are mostly applicable in the conceptual phase. Mission profiles are highly effective for gross analysis. Relative complexity is simple.</li> <li>•Mission Scenario. Is a detailed narrative description of the sequence of actions and events associated with the execution of a particular mission. A description of each distinct event occurring during the mission. The events should be described from the human's perspective as s/he interacts with the system. The scenarios should describe operator actions and system capabilities needed to complete the mission. The detail of the narrative will depend on its purpose. It is useful to describe all essential system functions that would be overlooked, such as failure modes and emergency procedures.</li> </ul> | Two methods, Mission Profile, and Mission Scenarios are especially useful for mission analysis. Alternative name for Mission Profile is Graphic Mission Profile. Alternative name for Mission Scenario is Narrative Mission Description. The information from the mission scenario can be used for Functional Flow Diagrams (FFD), Decision/Action Diagrams (DAD), and Action/Information Requirements for the system. |                         | 2 |   |   |   |   |   |   |         |             | defence, navy, space     | x      | x      | x      |            |  |  | <ul style="list-style-type: none"> <li>• [HEAT overview]</li> <li>• [MIL-HDBK, 1999]</li> <li>• [FAA HFW]</li> <li>• [Beevis, 1992]</li> </ul> |

| 512. | MMSA<br>(Man-Machine<br>System Analysis)  | Stat      | HRA     | 1983 | MMSA aims at identifying and reducing idle times for worker and/or machine, to minimize the overall operation cycle time. The MMSA steps are: 1) Definition: analysis of different types of human actions; 2) Screening: identify the different types of human interactions that are significant to the operation and safety of the plant; 3) Qualitative analysis: detailed description of the important human interactions and definition of the key influences; 4) Representation: modelling of human interactions in logic structures; 5) Impact integration: exploration of the impact of significant human actions; 6) Quantification: assignment of probabilities of interactions; 7) Documentation: making the analysis traceable, understandable and reproducible. | The MMSA steps can be arranged as a subset of the SHARP process, which is a qualitative screening method which is applied in HRA prior to full quantification; it filters out errors that are apparently incapable of affecting the system goal. |                         | 2 | 3 | 5 |   |   |   |   |         |                          | manufacturing,<br>maritime,<br>energy, nuclear | x      |        | x      |            |                             |  | • [Straeter, 2001] |
| 513. | Modelica  | Gen       | Mod     | 1997 | Modelica is an object-oriented, declarative, multi-domain modelling language for modelling of systems containing mechanical, electrical, electronic, hydraulic, thermal, control, electric power or process-oriented subcomponents. Focus is on differential equations.   | The Modelica language is developed by the non-profit Modelica Association, which also develops a Standard Library that contains over a thousand generic model components and functions in various domains.                                       |                         | 2 | 4 |   |   |   |   |   |         | manufacturing,<br>energy | x  |        |        |        |            |                             | • <a href="https://www.modelica.org/">https://www.modelica.org/</a>  |                    |
| 514. | Modelling   | Gen       | Mod     |      | A model is anything used in any way to represent anything else. A few examples are Computer models, Mathematical models, Scientific models, Logical models. There are many forms of modelling techniques that are used in system engineering. Failures, events, flows, functions, energy forms, random variables, hardware configuration, accident sequences, operational tasks, all can be modelled.   | Modelling is appropriate for any system or system safety analysis. See also Computer Modelling and simulation. | 517. | Monte Carlo Simulation                             | FTS    | Mod ?   | 1777 | The objective of Monte Carlo simulation is to obtain a quantitative outcome from a given model by translating variation or uncertainties in model inputs to variation or uncertainties in model outputs. Each input parameter of the model is assumed to be described by a probability density function (pdf). In a MC simulation, all model input parameters are given values which are selected from their respective pdfs, and the model is simulated to obtain an output result. This procedure is repeated a large number of times. The outcome is a large number of separate and independent model output results. These results are assembled into a probability distribution or expected value for the output parameter of interest.  | Reportedly, the method was first used by the Comte de Buffon, George Louis Leclerc, in 1777, to estimate the value for $\pi$ . The name stems from WW II, and was coined by Stanislaw Ulam, who claimed to be stimulated by playing poker; the name refers to the Monte Carlo Casino in Monte Carlo, Monaco. This method is often used when the underlying model is complex, nonlinear, or involves more than just a couple of uncertain parameters.   |                         |   |   |   | 4 | 5 |   |   |         |             |                                  |        |        |        |            |   | <ul style="list-style-type: none"> <li>• [EN 50128, 1996]</li> <li>• [MUFTIS3.2-I, 1996]</li> <li>• [Rakowsky]</li> <li>• [Sparkman, 1992]</li> <li>• [GAIN ATM, 2003]</li> <li>• [GAIN AFSA, 2003]</li> </ul> |   |   |
| 518. | MORS (Mandatory Occurrence Reporting Scheme)       | Dat    | Dat     | 1972 | Primary purpose is to secure free and uninhibited reporting, and dissemination of the substance of the reports, where necessary, in the interest of flight safety. It covers operators, manufacturers, maintenance, repair and overhaul, air traffic control services, and aerodrome operators. Only certain kinds of incidents, namely, those that are “endangering” or “potentially endangering,” are subject to mandatory reporting; others are not. Reporting of “day-to-day defects/incidents, etc” is discouraged. These are left to the CAA’s Occurrence Reporting Scheme.   | MORS was established by the United Kingdom Civil Aviation Authority (CAA) following a fatal accident in 1972.  |                         |   |   |   |   |   |   |   |         | 8           | aviation, ATM, airport, aircraft | x      |        |        | x          | x |  | <ul style="list-style-type: none"> <li>• [GAIN ATM, 2003]</li> <li>• [CAP 382, 2011]</li> </ul> |   |
| 519. | MORT (Management Oversight and Risk Tree Analysis) | Stat   | Ret     | 1972 | MORT technique is used to systematically analyse an accident in order to examine and determine detailed information about the process and accident contributors. To manage risks in an organisation, using a systemic approach, in order to increase reliability, assess risks, control losses and allocate resources effectively. Is standard fault tree augmented by an analysis of managerial functions, human behaviour, and environmental factors. MORT is accomplished using the MORT diagrams, of which there are several levels available. The most comprehensive has about 10,000 blocks, a basic diagram has about 300 blocks. It is possible to tailor a MORT diagram by choosing various branches of the tree and using only those segments. The MORT is essentially a negative tree, so the process begins by placing an undesired loss event at the top of the diagram used. The user then systematically responds to the issues posed by the diagram. All aspects of the diagram are considered and the “less than adequate” blocks are highlighted for risk control action. | Originally developed in 1972 for US nuclear industry. This is an accident investigation technique that can be applied to analyse any accident. Useful in project planning, functional specification of a target (sub)system, accident/incident analysis and safety programme evaluation. Since even the simplest MORT chart contains over 300 blocks, the full application of MORT is time-consuming and costly. Tools available. See also SMORT, Barrier Analysis, ETBA, HPIP, HSYS, ISA, STEP. |                         |   |   |   |   |   |   |   |         | 8           | nuclear, (space)                 | x      |        |        | x          | x | x  |   | <ul style="list-style-type: none"> <li>• [Bishop, 1990]</li> <li>• [FAA00]</li> <li>• [Kirwan &amp; Ainsworth, 1992]</li> <li>• [Kirwan, 1994]</li> <li>• [Leveson, 1995]</li> <li>• [ΣΣ93, ΣΣ97]</li> <li>• [FAA HFW]</li> </ul> |

| 526. | N out of M vote  | Step   | HwD     | 1981<br>?           | Aim of N out of M vote is to reduce the frequency and duration of system failure, to allow continued operation during test and repair. Voting is a fundamental operation when distributed systems involve replicated components (e.g. after Diverse Programming). Voting is defined as the number of redundant paths (N) required out of the total number of redundant paths (M) in order to carry out the (safety) function. For example, 2 out of 3 voting scheme means that if one of three components fails, the other two will keep the system operational. The hardware fault tolerance (HFT), which is defined as M-N, is a measure of redundancy.  | Used for systems where any break in service has serious consequences. 'N out of M' is usually denoted by 'NooM', e.g. as in 1oo2 or 2oo3. A variant is Adaptive Voting, which aims to avoid that fault masking ability deteriorates as more copies fail (i.e. faulty modules outvote the good modules). |                         |   |   |   |   |   |   | 6 |         |             | software               |        | x      |        |            |  |                             | • [Bishop, 1990]                  |
| 527. | NAIMS<br>(National Airspace Information Monitoring System) | Dat    | Dat     | 1985                | NAIMS is a Federal Aviation Administration program to collect, maintain and analyse aviation statistical information based on reports of accidents and incidents in the US national airspace system. NAIMS produces a monthly report available to the public, supplies data to NASDAC, and responds to public inquiries for safety information. Reported incidents are: 1. near mid-air collisions (NMAC's); 2. operational errors (OE's); 3. operational deviations (OD's); 4. pilot deviations (PD's); 5. vehicle/ pedestrian deviations (VPD's); 6. surface incidents (SI's); 7. runway incursions (RI's); 8. flight assists (FA's). The NAIMS monthly report monitors trends in and apportionment of each of these indicators. For example, operational error rates (OE's per 100,000 operations) are shown for each ATC facility. The original forms are maintained for five years. A database containing an electronic copy of each form is maintained indefinitely. | NAIMS is currently known as ATQA (Air Traffic Quality Assurance).   |                         |   |   |   |   |   |   |   |         | 8           | aviation, ATM, airport | x      |        | x      | x          |  |                             | • [GAIN ATM, 2003]<br>• [FAA HFV] |

| 530. | NARIM<br>(National Airspace Resource Investment Model)                      | Int    | Des,<br>OpR,<br>Dec | 1998         | NARIM aims at examining airspace concepts associated with future advances to the National Airspace System (NAS). It consists of three interrelated parts: 1) Operational modelling analyzes the movement of aircraft through the NAS to determine the impacts that new concepts, implemented through procedures and/or hardware, will have on the overall NAS performance. 2) Architectural/Technical modelling provides a means of assessing how procedural/ system changes affect the hardware/ software components of the NAS infrastructure (both FAA and users). 3) Investment analysis modelling provides a methodology to cost effectively trade between alternatives for a system, trade requirements within a system and across system and procedural investment alternatives, trade between services to be provided/included into the NAS, balance risk, and assess the investment decision as a part of a total research portfolio. | NARIM is developed jointly by the FAA Investment Analysis and Operations Research Directorate and NASA Interagency Integrated Product Team (IPT) for Air Traffic Management (ATM). |                         | 2 |   | 4 | 5 | 6 |   |   |         |              | aviation,<br>airport, ATM | x      | x      | x      | x          | x  | <ul style="list-style-type: none"> <li>• [Dorado-Usero et al, 2004]</li> <li>• [Sherali et al, 2002]</li> <li>• [FAA HFW]</li> </ul> |

Its aim is to evaluate new operational procedures, new controller assistance tools, and new human/machine interfaces. There are six AT consoles and up to 12 pseudo pilot positions, each of which can control up to 15 aircraft. The AT consoles and pseudo pilots are connected by a voice communication net. The computers driving each station are connected to the main NARSIM computer. The NARSIM software simulates most important aspects of a real air traffic control system, including realistic radar information. It has the capability to use actual recorded radar data, computer-generated data, pseudo pilot generated data, or combinations of the three.  | NARSIM has been developed by National Aerospace Laboratory NLR and is integrated with NLR's Tower Research Simulator (TRS).  |                         | 2 |   |   |   | 6 | 7 | 8 |         | ATM, airport | x                         |        | x      | x      |            | <ul style="list-style-type: none"> <li>• [GAIN ATM, 2003]</li> </ul> |  |

| 532. | NDI (Non-Destructive Inspection)   | Gen      | Hzi     | 1914 - 1918 war | Generic term rather than a specific technique. NDI can be defined as inspection using methods that in no way affect the subsequent use or serviceability of the material, structure or component being inspected. An NDI method explores a particular physical property of a material or component in an effort to detect changes in that property which may indicate the presence of some fault. Visual inspection is the most commonly used NDI technique.                           | NDI is commonly referred to as Non-destructive Testing (NDT) which is historically the original term used - NDI is the more commonly used term in the manufacturing environment where the testing of the suitability of materials to be used is often undertaken non-destructively. The "non-destructive" description was adopted to differentiate it from the various "destructive" mechanical tests already in use. The term Non-destructive Evaluation (NDE) is also used, most particularly in the sphere of R&D work in the laboratory. [NDT Test Methods] provides a list of NDT Test Methods. |                         |   | 3 |   |   |   |   |   |         |             |        | x      |        |        |            |  |  | <ul style="list-style-type: none"> <li>• [Hollamby, 1997]</li> <li>• [Wassell, 1992]</li> <li>• [NDT Test Methods]</li> </ul> |

| 534. | Neural Networks  | Math     | Mod     | 1890            | Neural networks are collections of mathematical models that emulate some of the observed properties of biological nervous systems and draw on the analogies of adaptive biological learning. The key element of the paradigm is the novel structure of the information processing system. It is composed of a large number of highly interconnected processing elements that are analogous to neurones and are tied together with weighted connections that are analogous to synapses. | The concept of neural networks started in the late 1800s as an effort to describe how the human mind performed. It was inspired by the way the densely interconnected, parallel structure of the mammalian brain processes information. In [May, 1997], neural networks are used to model human operator performance in computer models of complex man-machine systems. Sometimes referred to as Artificial Neural Network (ANN).  |                         |   | 4 |   |   |   |   |   |         |             |        | x      |        | x      |            |  | <ul style="list-style-type: none"> <li>• [May, 1997]</li> <li>• [FAA HFW]</li> </ul> |   |

| 535. | NextGen Future Safety Assessment Game                        | Int    | Dec      | 2011          | This methodology aims at identifying possible NextGen futures and to perform an initial expert based ranking of risk and prioritization for further analysis. Its key method is serious gaming and infrastructure design, to model the total system and its dynamics.   | NextGen is the name given to a new National Airspace System due for implementation across the United States in stages between 2012 and 2025. Serious gaming refers to simulations of real-world events or processes designed for the purpose of solving a problem.  |                         |   |   | 3 |   | 5 |   |   |         |             |        | (ATM)  | x      |        |            |   | x |   | • [Ancel et al, 2011]   |
| 536. | NFR (Non-Functional Requirements framework)                  | Stat   | SwD      | 1992          | NFR is a framework on Goal Modelling. The analysis begins with softgoals that represent NFR which stakeholders agree upon. These softgoals are then decomposed and refined to uncover a tree structure of goals and subgoals. Once uncovering tree structures, one tries to find interfering softgoals in different trees. These softgoal trees now form a softgoal graph structure. The final step in this analysis is to pick some particular leaf softgoals, so that all the root softgoals are satisfied.   | Softgoals are goals that are hard to express, but tend to be global qualities of a software system. These could be usability, performance, security and flexibility in a given system. The NFR approach evolved into the Goal-oriented Requirement Language (GRL). GRL is part of the ITU-T URN standard draft which also incorporates Use Case Maps (UCM). |                         |   |   |   |   |   | 6 |   |         |             |        | electronics  |        | x      |            |   |   |   | • [Mylopoulos et al, 1992]<br>• [Chung & Nixon, 1995]<br>• [Mylopoulos et al, 1999] |
| 537. | NGOMSL (Natural GOMS Language)                               | Stat   | Task     | 1988          | NGOMSL builds on CMN-GOMS by providing a natural-language notion for representing GOMS models, as well as a procedure for constructing the models. Under NGOMSL, methods are represented in terms of an underlying cognitive theory known as Cognitive Complexity Theory (CCT), which addresses a criticism that GOMS does not have a strong basis in cognitive psychology. This cognitive theory allows NGOMSL to incorporate internal operators such as manipulating working memory information or setting up subgoals. Because of this, NGOMSL can also be used to estimate the time required to learn how to achieve tasks. | Natural GOMS Language technique was developed by David Kieras in 1988. See also CAT, CPM-GOMS, CTA, GOMS, KLM-GOMS.   |                         | 2 |   |   |   |   |   |   |         |             |        | electronics, nuclear, defence, manufacturing, ergonomics |        |        |            | x | x |   | • [Kieras, 1996]<br>• [FAA HFW]<br>• [John & Kieras, 1996]<br>• [Morrison, 2003]    |
| 538. | NLA (Network Logic Analysis)                                 | Math   | Mod, HZI | 1972 or older | Network Logic Analysis is a method to examine a system in terms of a Boolean mathematical representation in order to gain insight into a system that might not ordinarily be achieved. Steps are: Describe system operation as a network of logic elements, and develop Boolean expressions for proper system functions. Analyse the network and/or expressions to identify elements of system vulnerability to mishap.   | The technique is appropriate to complex systems that can be represented in bi-model elemental form.   |                         | 2 |   |   |   |   |   |   |         |             |        | environment, defence, space                              | x      | x      |            |   |   |   | • [FAA00]<br>• [ΣΣ93, ΣΣ97]   |

| 541. | NOSS<br>(Normal Operations Safety Survey)   | Dat    | Dat     | 2003 | NOSS is a methodology for the collection of safety data during normal air traffic control (ATC) operations. By conducting a series of targeted observations of ATC operations over a specific period of time, and the subsequent analysis of the data thus obtained, the organisation is provided with an overview of the most pertinent threats, errors and undesired states that air traffic controllers must manage on a daily basis. One feature of NOSS is that it identifies threats, errors and undesired states that are specific to an organisation's particular operational context, as well as how those threats, errors and undesired states are managed by air traffic controllers during normal operations. The information thus obtained will enhance the organisation's ability to proactively make changes in its safety process without having to experience an incident or accident. | A normal ATC operation is defined as an operation during the course of which no accident, incident or event takes place of which the reporting and/or investigation are required under existing legislation or regulations. Training and check shifts are considered to be outside the scope of normal operations.  |                         |   |   |   |   |   |   |   |         |             | 8      | (ATM)  |        |        |            | x | x |   |  |  | • [NOSS] |  |
| 542. | NOTECHS<br>(Non Technical Skills)   | Tab    | HRA     | 1998 | Technique for assessing non-technical skills of crews. Focuses on the individual (pass or fail). The NOTECHS framework consists of four categories: Cooperation, Leadership and managerial skills, Situation awareness, Decision-making. Each category is subdivided into a number of elements. An individual is then assessed on each of the categories. The overall rating shows if the individual passes, or if further training is required.  | Developed in Europe for JAA. JAA intends to use NOTECHS as evaluation tool in the same way as they evaluate technical skills. "Oxford NOTECHS" is an adapted version developed in 2003 by University of Oxford for application to personnel in operating theatres of hospitals.   |                         |   |   |   |   |   |   |   |         |             |        | 5      |        |        |            |   |   | x |  |  |          | • [Verheijen, 2002]<br>• [Flin, 1998]<br>• [Avermaete, 1998]<br>• [JAR TEL, 2002]<br>• [McCulloch et al, 2009]<br>• [Mishra et al, 2009] |
| 543. | NSCA<br>(Nuclear Safety Culture Assessment)   | Tab    | Org     | 2009 | Aim is safety culture assessment in nuclear power plants. The process is comprised of nine elements: Process inputs; Nuclear safety culture monitoring panel; Site leadership team; Communication; Regulatory oversight; Corrective actions; Other input sources; Site response; External input.  |   |                         |   |   |   |   |   |   |   |         |             |        |        |        |        |            |   |   |   |  |  | x        | • [Mkrtychyan & Turcanu, 2012]   |
| 544. | NSCCA<br>(Nuclear Safety Cross- Check Analysis)   | Step   | SwD     | 1976 | The NSCCA provides a technique that verifies and validates software designs associated with nuclear systems. The NSCCA is also a reliability hazard assessment method that is traceable to requirements-based testing.  | At present applies to military nuclear weapon systems.  |                         |   |   |   |   |   |   |   |         |             |        |        |        |        |            |   |   |   |  |  |          | • [FAA AC431]<br>• [Rakowsky]<br>• [ΣΣ93, ΣΣ97]  |
| 545. | NTSB<br>Accident/Incident database<br>(National Transportation Safety Board Accident/Incident database) | Dat    | Dat     | 1967 | The NTSB accident and incident database is the FAA official repository of aviation accident data and causal factors. In this database, personnel categorize events as accidents or incidents. Since its inception, the NTSB has investigated more than 132,000 aviation accidents and thousands of surface transportation accidents. Accident Reports provide details about the accident, analysis of the factual data, conclusions and the probable cause of the accident, and the related safety recommendations. Most reports focus on a single accident, though the NTSB also produces reports addressing issues common to a set of similar accidents.  | Since 1967, the NTSB has investigated accidents in the aviation, highway, marine, pipeline, and railroad modes, as well as accidents related to the transportation of hazardous materials. Aviation accident reports from 1996 onwards are online at [NTSB Accidents]. FAA usage rules dictate using NTSB accident database as primary source for accidents, but to use FAA AIDS for incidents. |                         |   |   |   |   |   |   |   |         |             |        |        |        |        |            |   |   |   |  |  |          | • [NTSB Accidents]<br>• [ATO SMS Manual v3.0]<br>• [NTSB Home]   |

| 546. | Nuclear Criticality Safety                    | Step   | Mit      | 1983          | Nuclear criticality safety is dedicated to the prevention of an inadvertent, self-sustaining nuclear chain reaction, and with mitigating the consequences of a nuclear criticality accident. A nuclear criticality accident occurs from operations that involve fissile material and results in a release of radiation. The probability of such accident is minimised by analyzing normal and abnormal fissile material operations and providing requirements on the processing of fissile materials.   | All facilities that handle fissile material. See also Criticality Analysis or Criticality Matrix.  |                         |   |   |   |   |   |   | 6 |         |             | nuclear   | x      |        |        |            | x |   | <ul style="list-style-type: none"> <li>• [ΣΣ93, ΣΣ97]</li> <li>• [O'Neal et al, 1984]</li> <li>• [Lipner &amp; Ravets, 1979]</li> </ul> |
| 547. | Nuclear Explosives Process Hazard Analysis    | Step   | Mit      | 1997 or older | A nuclear explosive is an explosive device that derives its energy from nuclear reactions. Aim of Nuclear Explosives Process Hazard Analysis is to identify high consequence (nuclear) activities to reduce possibility of nuclear explosive accident.  | Nuclear or similar high risk activities. See also Process Hazard Analysis.   |                         |   |   | 3 |   |   |   | 5 |         |             | (nuclear) | x      |        |        |            | x |   | <ul style="list-style-type: none"> <li>• [ΣΣ93, ΣΣ97]</li> </ul>  |
| 548. | Nuclear Safety Analysis                       | Gen    | HZA, OpR | 1980 or older | The purpose is to establish requirements for contractors responsible for the design, construction, operation, decontamination, or decommissioning of nuclear facilities or equipment to develop safety analyses that establish and evaluate the adequacy of the safety bases of the facility/equipment. The DOE requires that the safety bases analysed include management, design, construction, operation, and engineering characteristics necessary to protect the public, workers, and the environment from the safety and health hazards posed by the nuclear facility or non-facility nuclear operations. The Nuclear Safety Analysis Report (NSAR) documents the results of the analysis.  | All nuclear facilities and operations. DOE (Department of Energy) and NRC (Nuclear Regulatory Commission) have rigid requirements.           |                         |   |   |   |   |   |   | 6 |         |             | nuclear   | x      |        |        |            | x | x | <ul style="list-style-type: none"> <li>• [FAA AC431]</li> <li>• [ΣΣ93, ΣΣ97]</li> </ul>   |

| 550. | OARU Model (Occupational Accident Research Unit Model) | Step   | Mod     | 1980 | Model for analysis of accidents. In this model a distinction is made between three phases in the accident process: two preinjury phases – the initial and concluding phase- followed by the injury phase, i.e. the pathogenic outcome of physical damage in a person. The initial phase starts when there are deviations from the planned or normal process. The concluding phase is characterised by loss of control and the ungoverned flow of energy. The injury phase starts when energies meet the human body and cause physical harm.  | Developed by U. Kjellén.   |                         |   |   |   |   |   |   |   |         |             |        |        |        |        |            |  | <ul style="list-style-type: none"> <li>• [Kjellen, 2000]</li> <li>• [Engkvist, 1999]</li> </ul>  |
| 551. | OATS (Operator Action Trees)                           | Stat   | HRA     | 1982 | Deals with operator errors during accident or abnormal conditions and is designed to provide error types and associated probabilities. The method employs a logic tree, the basic operator action tree, that identifies the possible postaccident operator failure modes. Three error types are identified: 1) failure to perceive that an event has occurred; 2) failure to diagnose the nature of event and to identify necessary remedies; 3) failure to implement those responses correctly and in timely manner. Next, these errors are quantified using time-reliability curves. |  |                         |   | 3 | 4 | 5 |   |   |   |         |             |        |        |        |        |            |  | <ul style="list-style-type: none"> <li>• [Kirwan &amp; Ainsworth, 1992]</li> <li>• [MUFTIS3.2-I, 1996]</li> <li>• [GAIN ATM, 2003]</li> <li>• [FAA HFW]</li> </ul> |
| 552. | OBJ  | Int    | Des     | 1976 | OBJ (not an acronym) is an algebraic Specification Language to provide a precise system specification with user feed-back and system validation prior to implementation.   | Introduced by Joseph Goguen in 1976. Powerful yet natural formal specification language for both large- and small-scale systems developments. Tools available. Software requirements specification phase and design & development phase. |                         |   |   |   |   |   | 6 |   |         |             |        |        |        |        |            |  | <ul style="list-style-type: none"> <li>• [Bishop, 1990]</li> <li>• [EN 50128, 1996]</li> <li>• [Rakowsky]</li> </ul>   |
| 553. | ObjectGEODE  | Int    | Des     | 1999 | ObjectGeode is a toolset dedicated to analysis, design, verification and validation through simulation, code generation and testing of real-time and distributed applications. It supports a coherent integration of complementary object-oriented and real-time approaches based on the UML, SDL and MSC standards languages. ObjectGeode provides graphical editors, a powerful simulator, a C code generator targeting popular real-time OS and network protocols, and a design-level debugger. Complete traceability is ensured from Requirement to code.                          | Developed by Verilog, which was bought by Telelogic in 1999, which was bought by IBM in 2007. It is reported that the ObjectGEODE tool is no longer commercialized or retained in another IBM product.                                   |                         |   |   |   |   |   |   | 7 |         |             |        |        |        |        |            |  | <ul style="list-style-type: none"> <li>• [Telelogic Objectgeode]</li> <li>• [Garavel, 2013]</li> </ul>   |
| 554. | Observational Techniques                               | Gen    | Dat     | 1990 | General class of techniques whose objective is to obtain data by directly observing the activity or behaviour under study. Examples of these techniques are direct visual observation, continuous direct observation, sampled direct observation, remote observation via closed-circuit television or video recording, participant observation, time-lapse photography.  | Observational techniques are often employed when other, more obtrusive techniques such as questionnaires or interviews, are not appropriate.   |                         |   |   |   |   |   |   |   | 7       |             |        |        |        |        |            |  | <ul style="list-style-type: none"> <li>• [Kirwan &amp; Ainsworth, 1992]</li> <li>• [FAA HFW]</li> </ul>  |

| 555. | Ofan  | Dyn    | Mod     | 1995          | Modelling framework describing human interaction with systems that have modes. Is based on the Statecharts and Operator Function Models (OFM). In Ofan, five concurrently active modules are used to describe the human-machine environment, namely the Environment, the Human Functions/Tasks, the Controls, the Machine, and the Displays. Applying the Ofan framework allows the identification of potential mismatches between what the user assumes the application will do and what the application actually does. The Ofan framework attempts to separate out the components of the whole environment.  | Developed by Asaf Degani. Ofan is Hebrew for a set of perpetuating wheels, referring to an event in one wheel affecting the adjacent wheel and so on, in perpetuum.   |                         | 2 | 3 | 4 |   |   |   |   |         |             |                 | electronics, road, healthcare, aviation, chemical | x      |        | x          |  |   |   | <ul style="list-style-type: none"> <li>• [Andre &amp; Degani, 1996]</li> <li>• [Degani, 1996]</li> <li>• [Degani &amp; Kirlik, 1995]</li> <li>• [Smith et al, 1998]</li> </ul> |
| 556. | Off-Hour Surveillance Assessment Decision Aid | Step   | HZA     | 2006 or older | The Off-Hour Surveillance Decision Aid is designed to assist in identifying risk and evaluating the effectiveness of air carrier activities conducted during off hours. Sufficient off-hour surveillance must occur to: a) Know what types and levels of activity are conducted during off-hours. b) Understand how the air carrier is managing and supervising off-hour activities, especially the interface with outsource maintenance and other contracted activities. c) Determine if the air carrier's processes and controls are sufficient to detect and correct any risks inherent with off-hour activities. d) Determine if the off-hour activities present a greater risk than activities done during normal FAA duty hours. | An example of off-hour air carrier activity in the air carrier flight/ground operations arena might be training that is conducted during off hours (midnight shift) or flight operations primarily conducted outside of normal FAA duty hours (e.g., overnight cargo operations). |                         |   | 3 |   |   |   |   |   |         |             | aviation        | x   |        |        |            |  | x | <ul style="list-style-type: none"> <li>• [FAA FSIMS, 2009]</li> <li>• [Notice 8300.123]</li> </ul>  |  |
| 557. | OFM (Operator Function Model)                 | Stat   | Task    | 1987          | Describes task-analytic structure of operator behaviour in complex systems. The OFM is focused on the interaction between an operator and automation in a highly proceduralised environment, such as aviation. The OFM is a structured approach to specify the operator tasks and procedures in a task analysis framework made up of modes and transitions. Using graphical notation, OFM attempts to graph the high level goals into simpler behaviours to allow the supervision of the automation.   | The power of OFM is based upon several important observations: the event-driven nature of automation, the proceduralised nature of high risk tasks, and the fact that many of the transitions and decisions made during system operation are discrete in nature. | 558. | OHHA<br>(Occupational Health Hazard Analysis)                   | Tab    | HZA      | 1971          | Is carried out to identify occupational health-related hazards and to recommend measures to be included in the system, such as provision of ventilation, barriers, protective clothing, etc., to reduce the associated risk to a tolerable level. Is carried out by means of audit and checklists.   | Occupational health and safety is a cross-disciplinary area concerned with protecting the safety, health and welfare of people engaged in work or employment. The goal of the programs is to foster a safe work environment. OSHA (Occupational Safety and Health Administration) have been regulating occupational safety and health since 1971. See also Systematic Occupational Safety Analysis. |                         |   |   | 3 |   |   | 6 |   |         |             | defence, mining        | x      |        | x      | x          |  |  | <ul style="list-style-type: none"> <li>• [DS-00-56, 1999]</li> <li>• [ΣΣ93, ΣΣ97]</li> </ul> |
| 559. | OMAR<br>(Operator Model Architecture)                           | FTS    | HFA      | 1993          | OMAR is a modelling and simulation tool that can generate high fidelity computer models of human behavior, as well as state-of-the-art intelligent agents for use in synthetic environments, distributed simulations, and information systems. OMAR aims at supporting the development of knowledge-based simulations of human performance, with a focus on the cognitive skills of the human operator. It models situated-cognition, where a human dynamically shifts between goals based upon events occurring in the environment. | Was developed for the US Air Force. OMAR has evolved into a distributed architecture version, D-OMAR, developed by BBN Technologies, which provides a suite of software tools from which to implement alternate architectures.  |                         | 2 |   | 4 |   |   |   |   |         |             | defence, ATM, aviation |        |        | x      |            |  | <ul style="list-style-type: none"> <li>• [Deutsch et al, 1993]</li> <li>• [FAA HFW]</li> <li>• [Pew, 2008]</li> <li>• [Leiden &amp; Best, 2005]</li> <li>• [Morrison, 2003]</li> </ul> |  |

Andersson (Lund Institute of Technology, Sweden). OmSim is an environment for modelling and simulation based on OMOLA.  |                         |   |   | 4 | 5 |   |   |   |         |             | energy                 | x      |        |        |            |  | <ul style="list-style-type: none"> <li>• [Andersson, 1993]</li> <li>• [OmolaWeb]</li> </ul>  |  |
| 561. | OOD and Programming<br>(Object-oriented Design and Programming) | Gen    | Des      | 1966 or older | Uses "objects" – data structures consisting of data fields and methods together with their interactions – to design applications and computer programs. Programming techniques may include features such as data abstraction, encapsulation, modularity, polymorphism, and inheritance. Aim is to reduce the development and maintenance costs and enhance reliability, through the production of more maintainable and re-usable software.  | Useful as one possible option for the design of safety-related systems. Also for construction of prototypes. Related to JSD and OBJ. Tools available. Software design & development phase. Also referred to as OOD/OOA, i.e. Object Oriented Design / Object Oriented Analysis.   |                         |   |   |   |   |   | 6 |   |         |             | software               |        | x      |        |            |  | <ul style="list-style-type: none"> <li>• [Bishop, 1990]</li> <li>• [EN 50128, 1996]</li> <li>• [Rakowsky]</li> </ul>   |  |

| 563. | Opportunity Assessment      | Int    | Org. Dec | 2000 or older | Opportunity Assessment aims at identifying opportunities to expand the capabilities of the organisation and/or to significantly reduce the operational cost of risk control procedures. It involves five key steps: 1) Operational areas that would benefit from expanded capabilities are identified and prioritized; areas where risk controls are consuming extensive resources or are constraining operation capabilities are listed and prioritized. 2) In areas where opportunities exist, analyze for risk barriers. 3) Attack the barriers by using the ORM (operational risk management) process: reassess the hazards, apply improved risk controls, improve implementation of existing controls. 4) When available risk management procedures don't appear to offer any breakthrough possibilities, seek out new ORM tools using benchmarking procedures or innovate new procedures. 5) Exploit any breakthroughs by pushing the operational limits or by cost saving until a new barrier is reached. The cycle then repeats and a process of continuous improvement begins. |   |                         |   |   |   |   | 6 |   | 8 | manufacturing, management |             |        |        |        | x   | <ul style="list-style-type: none"> <li>[FAA00]</li> </ul> |
| 564. | OPSNET (Operations Network) | Dat    | Dat      | 1988          | OPSNET is an official database of U.S. NAS (National Airspace System) air traffic operations and delay data. The data collected through OPSNET are used to analyze the performance of the FAA's ATC facilities traffic count and delay information, ATCT and Terminal Radar Approach Control operations, etc. OPSNET records the following information and data: Airport Operations; Tower Operations: TRACON Operations; Total Terminal Operations; Center Aircraft Handled; Facility Information; Delays.   | OPSNET was created in 1988 and was regularly updated. The latest revision is from 2008, during which historical OPSNET operations data dating back to 1990 have been converted to be consistent with the revised air traffic count reporting standards. From October 22, 2007, all ATC facilities with the exception of flight service stations (FSS) are required to record OPSNET data and transmit data to the ATO System Operations, Quality Assurance (QA) office daily. The ATCSCC QA then processes the data and stores them into the OPSNET database. |                         |   |   |   |   |   |   | 8 | (ATM)                     |             |        |        | x      | <ul style="list-style-type: none"> <li>[ATO SMS Manual v3.0]</li> <li>[FAA OPSNET]</li> <li>[FAA OPSNET Manual]</li> <li>[FAA Order JO 7210.55F]</li> </ul> |   |

| 565. | OPT<br>(Outsource Oversight Prioritization Tool) | Dat    | Dat, Mit      | 2008 or older | The OPT is used for planning surveillance of air carrier maintenance providers. It allows for prioritization of air carrier maintenance providers to help determine specific data collection requirements. The OPT will assist the principal inspector (PI), other assigned inspectors, supervisors, and managers in identifying areas of concern or criticality, allowing them to target resources toward air carrier maintenance providers with the highest risk. The OPT is also used as part of the Enhanced Repair Station and Air Carrier Outsourcing Oversight System, along with the Repair Station Assessment Tool and the Repair Station Risk Management Process. The data resulting from the use of these tools resides in Safety Performance Analysis System (SPAS) and may provide valuable information to help an air carrier PI plan data collection activities for air carrier maintenance providers. | Only one OPT is required for each air carrier.   |                         |   | 3 |   |   | 6 |   |  |  | aviation    | x      |        |        | x   | x  | • [FAA FSIMS, 2009] |
| 566. | Organisational learning                          | Gen    | Dat, Mit, Org | 1978          | Organisational learning is the process of “detection and correction of errors.” Organisations learn through individuals acting as agents for them: The individuals’ learning activities, in turn, are facilitated or inhibited by an ecological system of factors that may be called an organisational learning system.   | Term is introduced in the 1970s by Chris Argyris and Donald Schön. Four constructs are integrally linked to organisational learning: knowledge acquisition, information distribution, information interpretation, and organisational memory.   |                         |   |   |   |   |   | 8 |  | ATM, aviation, rail, nuclear, chemical, oil&gas, defence, healthcare, police |             |        |        |        | x   | • Huge reference list on OL: [Polat, 1996] |                     |
| 567. | ORM<br>(Operational Risk Management)             | Int    | Dec           | 1991 or older | ORM is a decision-making tool to systematically help identify operational risks and benefits and determine the best courses of action for any given situation. The ORM process comprises six steps. 1) Using a Task analysis as input, identify Hazards and their causes; 2) Assess the Risk; 3) Identify and analyze Risk Control Measures and prioritize those risk controls that will reduce the risk to an acceptable level; 4) Make Control Decisions; 5) Implement Risk Controls, by making the implementation directive clear, establishing accountability, and getting approval, commitment and support at the appropriate management level; 6) Supervise and Review, and establish a feedback system.  | In contrast to an Operating and Support Hazard Analysis (O&SHA), which is performed during development, ORM is performed during operational use. The ORM concept grew out of ideas originally developed to improve safety in the development of new weapons, aircraft and space vehicles, and nuclear power. The US Army adopted Risk Management in 1991 to reduce training and combat losses. [FAA00] lists several techniques that can be used to support the process. |                         |   |   |   | 7 |   |   | defence, navy, finance, food, security, nuclear, oil&gas, aviation, healthcare | x  | x           | x      | x      | x      | • [AFP90-902, 2000]<br>• [FAA00]<br>• [ORM web] |  |                     |

| 568. | ORR<br>(Operational Readiness Review)                    | Step   | Dec     | 1997<br>or<br>older | An ORR is a structured method for determining that a project, process, facility or software application is ready to be operated or occupied (e.g. a new Air Traffic Control Centre; a new tower; a new display system, etc.). The ORR is used to provide a communication and quality check between Development, Production, and Executive Management as development is in the final stages and production implementation is in progress. This process should help management evaluate and make a decision to proceed to the next phase, or hold until risk and exposure can be reduced or eliminated. This review process can also be used to evaluate post operational readiness for continuing support and will also provide information to make necessary system/procedural modifications, and error and omissions corrections. | DOE (Department of Energy) requirement. Systematic approach to any complex facility. The details of the ORR will be dependent on the application.  |                         |   |   |   |   |   |   |   |         |             |        |        |        |        |            |  | <ul style="list-style-type: none"> <li>• [DOE-3006, 2000]</li> <li>• [Dryden-ORR]</li> <li>• [ΣΣ93, ΣΣ97]</li> <li>• [Enterprise-ORR]</li> <li>• [NNSA-ORR]</li> </ul>   |

| 569. | OSD<br>(Operational Sequence Diagram)                    | Stat   | Task    | 1960                | An operational sequence is any sequence of control movements and/or information collecting activities, which are executed in order to accomplish a task. Such sequences can be represented graphically in a variety of ways, known collectively as operational sequence diagrams. Examples are the Basic OSD, the Temporal OSD, the Partitioned OSD, the Spatial OSD, Job Process Charts.  | Developed by F. Brooks for weapons industry. Operational Sequence Diagrams are extended (more detailed) forms of Flow Process Charts. Is useful for the analysis of highly complex systems requiring many time critical information-decision-action functions between several operators and equipment items. Sometimes referred to as SAT Diagram (Sequence and Timing Diagram) or Task Allocation Charts. |                         | 2 |   | 4 |   |   |   |   |         |             |        |        |        |        |            |  | <ul style="list-style-type: none"> <li>• [HEAT overview]</li> <li>• [Kirwan &amp; Ainsworth, 1992]</li> <li>• [MIL-HDBK, 1999]</li> <li>• [FAA HFW]</li> <li>• [Brooks, 1960]</li> <li>• [Beevis, 1992]</li> </ul> |

| 570. | OSP<br>(Oversee System Performance)                           | Int    | OpR        | 2009          | OSP is aimed at oversight of system performance and risk by balancing safety, business effectiveness, and stakeholder service objectives of the airworthiness organization. The functions defining the process are: (1) Collect data from various sources: process measures, non-process measures, risk measures; (2) Determine performance status and monitor risk: Data are gathered and are analyzed to determine if the process and non-process measures are within their thresholds; (3) In-depth analysis: If the measures are out of tolerance with the thresholds, then the data are further analyzed using different techniques in order to find trends, patterns, or causes, and then solutions; (4) Synthesis of solutions: Quantitative and qualitative solutions are integrated to enable the creation of the best solution given the consequences; (5) Management reviews and initiate corrective action: Reports are generated and shared with management. Corrective action solutions are prioritized and presented for review and consideration; (6) Report Results: The analysis results are finalized and posted to an organization dashboard for review. Data is archived and organized for the next analysis cycle. |   |                         |   | 3 |   |   |   |   |   | 8       | (aircraft)                            | x      |        |        |        |            |   | • [FAA ASKME]              |
| 571. | OSTI<br>(Operant Supervisory Taxonomy Index)                  | Tab    | Org        | 1986          | Analysis framework that assesses the safety culture health of the organisation by looking for the presence or absence of indicators of safety performance. Uses a standardized taxonomy of behaviors as the basis for categorizing and describing behaviors exhibited by managers and supervisors.   | Developed by Judith Komaki. Qualitative.  |                         |   |   |   |   |   |   |   | 8       | management, nuclear, police           |        |        |        |        |            | x   | • [Kennedy & Kirwan, 1998] |
| 572. | OTA<br>(Operator Task Analysis)                               | Step   | Task       | 1987 or older | Operator Task Analysis is a method to evaluate a task performed by one or more personnel from a safety standpoint in order to identify undetected hazards, develop note / cautions / warnings for integration in order into procedures, and receive feedback from operating personnel. Also known as Procedure Analysis, which is a step-by-step analysis of specific procedures to identify hazards or risks associated with procedures.  | Applicable to any process or system that has a logical start/stop point or intermediate segments, which lend themselves to analysis. This methodology is appropriate to any operation that has a human input. Other name for Procedure Analysis and often referred to as Task Analysis. |                         |   | 3 |   |   |   |   |   |         | ATM, defence, navy, nuclear           |        |        | x      | x      |            | • [FAA00]<br>• [Leveson, 1995]<br>• [ΣΣ93, ΣΣ97]                                    |                            |
| 573. | OWAS Method<br>(Ovako Working posture Analysis System Method) | Step   | HFA , Task | 1977          | Movement and posture analysis. Aims to limit physiological costs and prevent disease. Goal: Work protection to prevent occupational diseases; Approach: Evaluation and combination of data matrices of postures and movements, analysis of frequencies, and derives necessities and measures for design; Describes: Working postures and movements; Frequency in a task structure; Assignment of tasks into the work segment; Necessity of design interventions; Distribution of movements over the body; Weights handled and forces exerted.  | Developed in the Finnish steel industry (Ovako Oy) between 1974-78 and later enhanced by the Finnish Centre for Occupational Safety.  |                         |   |   |   | 5 | 6 |   |   |         | manufacturing, ergonomics, healthcare |        |        | x      |        |            | • [FAA HFW]<br>• [Luczak, 1997]<br>• [Laurig & Rombach, 1989]<br>• [Stoffert, 1985] |                            |

| 574. | Pareto Chart   | Tab       | Dec             | 1906          | The Pareto chart is a specialized version of a histogram that ranks the categories in the chart from most frequent to least frequent. A Pareto Chart is useful for non-numeric data, such as "cause", "type", or "classification". This tool helps to prioritize where action and process changes should be focused. If one is trying to take action based upon causes of accidents or events, it is generally most helpful to focus efforts on the most frequent causes. Going after an "easy" yet infrequent cause will probably not reap benefits.   | Named after Vilfredo Federico Damaso Pareto (1848 – 1923), who developed this chart as part of an analysis of economics data. He determined that a large portion of the economy was controlled by a small portion of the people within the economy. The "Pareto Principle" (later generalised by Joseph M. Juran) states that 80% of the problems come from 20% of the causes. |                         |   |   |   |   | 5 | 6 |   |         |                    | finance, management, manufacturing, social | x      |        |        | x          |  |                                      | • [FAA HFW]                         |
| 575. | PARI method (Precursor, Action, Result, and Interpretation Method) | Dat, Stat | Mit, Task, Trai | 1995          | In the PARI method, subject-matter experts are consulted to identify which issues to probe, and to aid in eliciting cognitive information from other subject-matter experts. For example, subject-matter experts may be asked to generate lists of potential equipment malfunctions and then engage in group discussions to reach agreement regarding a set of malfunction categories. Experts then design representative scenarios illustrating each category of malfunction. These scenarios are used to elicit information from a different set of subject-matter experts regarding how they would approach the situation presented in each scenario. Each expert is asked focused questions to identify actions or solution steps and the reasons (precursors) for those actions. The expert is then asked to interpret the system's response to his/her actions. The knowledge gathered in the interviews is represented using flow charts, annotated equipment schematics, and tree structures. | Cognitive Task Analysis technique developed at Brooks Air Force base. The PARI method is particularly useful in the development of training programs.  |                         |   | 3 | 4 |   |   | 6 |   |         |                    | defence, healthcare                        |        |        | x      |            |  |                                      | • [Hall et al, 1995]<br>• [FAA HFW] |
| 576. | Particular Risk Analysis   | Step      | HZA             | 1987          | Common cause analysis related technique. Defined as those events or influences outside the system itself. For example, fire, leaking fluids, tire burst, High Intensity Radiated Fields (HIRF), exposure, lightning, uncontained failure of high energy rotating fields, etc. Each risk should be the subject of a specific study to examine and document the simultaneous or cascading effects, or influences, that may violate independence.  | Is the second activity in a Common Cause Analysis; Zonal Analysis being the first and Common Mode Analysis being the third.  |                         |   | 3 |   |   |   |   |   |         | aircraft           | x  |        |        |        |            |  | • [Mauri, 2000]<br>• [ARP 4761]      |                                     |

| 578. | Parts Count method and Parts Stress method             | Step   | HwD     | 1981          | Aims at approximating the reliability of a system. In the Parts Count method, the base failure rates of all components in the system are summed. The rates may be weighted by 'quality factors' of the components, if known. Then the mean time between failures (MTBF) equals 1 divided by this sum. In the Parts Stress method, there are additional weights for stress levels each component is subjected to.  | It assumes that every subsystem failure can lead to total system failure. Used for electronic systems. Parts Count is used in early design phase; Parts Stress is used in detailed design.  |                         |   |   |   |   | 5 |   |   |         |             |        |  | electronics, defence, manufacturing, space, nuclear | x      |            |   |   |   |  | <ul style="list-style-type: none"> <li>[FT handbook, 2002]</li> <li>[MIL-217]</li> <li>[MUFTIS3.2-I, 1996]</li> </ul> |
| 579. | PAS (Pseudo Aircraft Systems)                          | RTS    | Trai    | 1990 or older | PAS is an air traffic control (ATC) simulator with a high-fidelity piloting system designed to simulate the flight dynamics of aircraft in controlled airspace. Realistic air traffic scenarios can be created for advanced automated ATC system testing and controller training. With PAS, researchers can examine air traffic flow in real time. PAS gives researchers the ability to provide air traffic control instructions to simulated aircraft, and receive verbal feedback from PAS operators ("pseudo-pilots") on a simulated radio network and visual feedback through a simulated radar display. PAS consists of three major software components: Simulation Manager, Pilot Manager, and one or more Pilot Stations. They combine to provide dynamic real-time simulations, robust piloting capabilities, and realistic aircraft modelling. | Supported by NASA Ames Research Center.   |                         |   |   |   |   |   |   |   | 7       |             |        | (ATM)  |   |        |            | x | x |   |  | <ul style="list-style-type: none"> <li>[GAIN ATM, 2003]</li> <li>[PAS web]</li> </ul>                                 |
| 580. | PC (Paired Comparisons)                                | Step   | Par     | 1927          | Estimates human error probabilities by asking experts which pair of error descriptions is more probable. Result is ranked list of human errors and their probabilities. The relative likelihoods of human error are converted to absolute human error probabilities assuming logarithmic calibration equation and two empirically known error probabilities.  | Developed by L.L. Thurstone in 1927. Does not restrict to human error only. Can be used together with APJ. Sometimes referred to as Pairwise comparison.  |                         |   |   |   |   | 5 |   |   |         |             |        | social, management, ATM, healthcare, nuclear | x   |        | x          |   |   |   | <ul style="list-style-type: none"> <li>[Humphreys, 1988]</li> <li>[Kirwan, 1994]</li> <li>[MUFTIS3.2-I, 1996]</li> <li>[Hunns, 1982]</li> </ul>  |   |
| 581. | PDARS (Performance data analysis and Reporting System) | Min    | Dat     | 1998          | Aim of PDARS is to provide Performance measurement metrics for the Federal Aviation Administration (FAA) at the national, as well as field level (individual en route and terminal facilities). PDARS collects and processes operational data (including aircraft tracks) and provides information to the users relevant to the air traffic system performance on a daily basis. 'TAP clients' are maintained at each facility site to continuously collect selective radar data, the data is processed and daily reports are generated, daily data is then sent to a central site for storage where the user can retrieve historical data, as well as conduct trend analysis.  | See also GRADE, SIMMOD. Work on PDARS started in 1997. A first lab prototype, supporting off-line data processing, was demonstrated in 1998. The first live radar data tap was brought on line at the Southern California TRACON (SCT) in 1999. |                         |   |   |   |   |   |   | 7 |         |             | ATM    |  |   |        |            |   | x | x | <ul style="list-style-type: none"> <li>[SAP15]</li> <li>[GAIN ATM, 2003]</li> <li>[Braven &amp; Schade, 2003]</li> <li>[MtS, 2010]</li> <li>[SoW, 2010]</li> <li>[ATAC-PDARS]</li> </ul> |   |

| 582. | PDP (Piecewise Deterministic Markov Process) | Math   | Mod      | 1984          | A PDP is a process on a hybrid state space, i.e. a combination of discrete and continuous. The continuous state process flows according to an ordinary differential equation. At certain moments in time it jumps to another value. The time of jump is determined either by a Poisson point process, or when the continuous state hits the boundary of an area.  | Developed by Mark H.A. Davis in 1984. Through the existence of equivalence relations between PDP and DCPN (Dynamically Coloured Petri Nets), the development of a PDP for complex operations can be supported by Petri nets.     |                         |   |   |   | 4 |   |   |   |         |             |        |        |        |        |            |  | <ul style="list-style-type: none"> <li>[Davis, 1984]</li> <li>[Everdij &amp; Blom, 2003]</li> <li>[Everdij &amp; Blom, 2005]</li> </ul>  |
| 583. | PEAT (Procedural Event Analysis Tool)        | Step   | Mit, Ret | 1999          | PEAT is a structured, cognitively based analytic tool designed to help airline safety officers investigate and analyse serious incidents involving flight-crew procedural deviations. The objective is to help airlines develop effective remedial measures to prevent the occurrence of future similar errors. The PEAT process relies on a non-punitive approach to identify key contributing factors to crew decisions. Using this process, the airline safety officer would be able to provide recommendations aimed at controlling the effect of contributing factors. PEAT includes database storage, analysis, and reporting capabilities.   | Boeing made PEAT available to the airline industry in 1999. The PEAT program has benefited from lessons learned by its sister program, Maintenance Error Decision Aid (MEDA), which Boeing has provided to operators since 1995. |                         |   |   |   |   |   |   |   |         |             |        |        |        |        |            |  | <ul style="list-style-type: none"> <li>[HIFA Data]</li> <li>[GAIN AFSA, 2003]</li> <li>[FAA HFW]</li> <li>[GAIN example-PEAT]</li> </ul> |
| 584. | Performance Modelling                        | Gen    | Mod      | 1961 or older | Aim is to ensure that the working capacity of the system is sufficient to meet the specified requirements. The requirements specification includes throughput and response requirements for specific functions, perhaps combined with constraints on the use of total system resources. The proposed system design is compared against the stated requirements by 1) defining a model of the system processes, and their interactions; 2) identifying the use of resources by each process; 3) Identifying the distribution of demands placed upon the system under average and worst-case conditions; 4) computing the mean and worst-case throughput and response times for the individual system functions.  | Valuable provided modelling limitations are recognised. Tools available. See also Computer Modelling and simulation. See also Modelling.   |                         |   |   |   |   | 5 |   |   |         |             |        |        |        |        |            |  | <ul style="list-style-type: none"> <li>[Bishop, 1990]</li> <li>[EN 50128, 1996]</li> <li>[Rakowsky]</li> </ul>                           |
| 585. | Performance Requirements Analysis            | Step   | Val      | 1995 or older | In this analysis, performance requirements are interactively developed across all identified functions based on system life cycle factors. They are characterized in terms of the degree of certainty in their estimate, the degree of criticality to system success, and their relationship to other requirements. Each of the performance requirements is examined in turn to determine: 1) the success criteria to be obtained; 2) whether a measure against the success criteria can be obtained; 3) the potential accuracy of such measurements; 4) the project stages at which the measurements can be estimated; 5) the project stages at which measurements can be made. The practicability of each performance requirement is then analysed. | Performance Requirements refer to the extent to which a mission or function must be executed; generally measured in terms of quantity, quality, coverage, timeliness or readiness.   | 1                       |   |   |   |   |   |   |   |         |             |        |        |        |        |            |  | <ul style="list-style-type: none"> <li>[EN 50128, 1996]</li> <li>[Rakowsky]</li> </ul>   |

| 586. | PERT<br>(Program Evaluation Review technique) | Stat      | Task    | 1957          | PERT is a method to analyze the involved tasks in completing a given project, especially the time needed to complete each task, and to identify the minimum time needed to complete the total project. A PERT shows all the tasks, a network that logically connects the tasks, time estimates for each task and the time critical path.   | Developed by US navy in 1950s. It is commonly used in conjunction with the critical path method (CPM).  |                         | 2 |   |   |   |   |   |   |         |             | navy, management, leisure   | x      | x      | x      | x          | x | • Internet  |
| 587. | PET<br>(Project Evaluation Tree)              | Stat      | OpR     | 1989          | PET is a review and inspection tool that aims to provide an in-depth evaluation or analysis of a project or operation. The general approach is an analytical tree, which is used as a graphic checklist that helps to identify each procedure, individual/organisation, facility or piece of equipment to be analysed. PET is divided into three basic branches: Procedures, Personnel, Plant and hardware. It requires as input information regarding hardware, facilities, environment, policies and procedures, personnel, implementation plans, job descriptions, organisation charts, training records, interviews, drawings and specifications, test plans and records, etc.   | PET is best suited for performing Operating Hazard Analysis or Accident Analysis. PET was developed as a less complex version of MORT.  |                         |   |   | 4 |   |   |   |   |         |             | (space), (defence)  | x      |        |        | x          |   | • [FAA00]<br>• [PET Purpose]<br>• [Lewis & Haug, 2009]  |
| 588. | Petri Nets                                    | Stat, Dyn | Mod     | 1962 from     | A Petri Net is a bi-partite graph of Places and Transitions, connected by Arcs. A token inside a place denotes that the corresponding discrete state is the current one. Petri Nets can be used to model system components, or sub-systems at a wide range of abstraction levels; e.g. conceptual, top-down, detail design, or actual implementations of hardware, software or combinations. The best known Petri net is named Place/Transition net (P/T net). This basic Petri Net models discrete state space systems only, and no random inputs. Numerous extensions exist through which other states and stochastic inputs can be modelled. Some notable extensions are Time (transitions fire not immediately but after waiting some time; this time may be constant or stochastic), Colour (tokens have a colour or value, which may be constant or even changing through time), Different types of arcs, different types of transitions or places. The Petri Net formalism allows to specify in a compositional way an unambiguous mathematical model of a complex system. For different Petri Net extensions, one-to-one mappings with mathematical formalisms are known, by means of which the advantages of both Petri Nets and these mathematical formalisms can be combined. | Petri nets were first developed by C.A. Petri in 1962. P/T nets are a special case of SSG. Plenty of tools available, also free. A useful advantage of Petri nets is the compositional specification power. GSPN (Generalised Stochastic Petri Nets) have been used to model an ATC technical support system). SPN (Synchronised Petri Network) has been used for modelling Human Operator tasks. Petri net extensions that have been developed and used in safety assessments for complex air traffic operations are DCPN and SDCPN. |                         |   |   | 4 | 5 |   |   |   |         |             | aviation, ATM, airport, defence, navy, space, rail, road, maritime, management, nuclear, chemical, oil&gas, manufacturing, healthcare, finance, electronics | x      | x      | x      | x          | x | • Huge amount of literature available, see for an overview e.g. [PetriNets World]<br>• [Abed & Angue, 1994]<br>• [Bishop, 1990]<br>• [EN 50128, 1996]<br>• [FAA AC431]<br>• [FAA00]<br>• [Kirwan & Ainsworth, 1992]<br>• [MUFTIS3.2-I, 1996]<br>• [ΣΣ93, ΣΣ97]<br>• [FAA HFW] |
| 589. | PFD<br>(Process Flow Diagram)                 | Stat      | Mod     | 1988 or older | A PFD displays the relationship between major equipment of a plant facility, such as process piping, control valves, recirculation systems. It does not show minor details such as piping details and designations.  | Used in chemical and process engineering. See also FPC (Flow Process Chart), which is used for physical processes.  |                         | 2 |   |   |   |   |   |   |         |             | oil&gas, chemical, food   | x      |        |        |            |   | • [Luyben & Wenzel, 1988]<br>• [Gow, 2003]  |

| 590. | PHA<br>(Preliminary Hazard Analysis)                                  | Tab    | HzA              | 1966                | Identification of unwanted consequences for people as result of disfunctioning of system. Aim is to determine during system concept or early development the hazards that could be present in the operational system in order to establish courses of action. Sometimes it consists of PHI and HAZOP and/or FMEA. The PHA is an extension of a Preliminary Hazard List. As the design matures, the PHA evolves into a system of sub-system hazard analysis.                                     | PHA was introduced in 1966 after the US Department of Defense requested safety studies to be performed at all stages of product development. PHA is considered for specification of systems which are not similar to those already in operation and from which much experience has been gained. Design and development phase. Use with FTA, FMEA, HAZOP. Initial effort in hazard analysis during system design phase. Emphasis on the hazard and its effects. Inductive and deductive. |                         |   |   | 3 |   |   |   |   |         |             |        |        |        |        |            |  |  | <ul style="list-style-type: none"> <li>• [Bishop, 1990]</li> <li>• [FAA AC431]</li> <li>• [FAA00]</li> <li>• [FAA tools]</li> <li>• [Mauri, 2000]</li> <li>• [MUFTIS3.2-I, 1996]</li> <li>• [ΣΣ93, ΣΣ97]</li> <li>• [SRM Guidance, 2007]</li> <li>• [FT handbook, 2002]</li> </ul> |
| 591. | PHASER<br>(Probabilistic Hybrid Analytical System Evaluation Routine) | Stat   | HzA              | 1996                | Software tool that solves the top event probability of a system fault tree. The basic concepts involve scale factors and confidence factors that are associated with the stochastic variability and subjective uncertainty (which are common adjuncts used in PSA), as well as safety risk extremes. Can be used for importance and sensitivity analysis, which help point out where any major sources of safety concern arise and where any major sources of uncertainty reside, respectively. | Implemented at Sandia National Labs, USA. The term hybrid in the name refers to events that are neither completely subjective nor completely stochastic. Uses fuzzy algebra. See also FTA.  |                         |   |   |   |   |   | 5 | 6 |         |             |        |        |        |        |            |  |  | <ul style="list-style-type: none"> <li>• [Cooper, 1996]</li> <li>• [ΣΣ93, ΣΣ97]</li> </ul>   |
| 592. | PHEA<br>(Predictive Human Error Analysis technique)                   | Tab    | HRA<br>,<br>Task | 1993                | Simplified version of the earlier SHERPA. Comprises an error checklist. Focuses on particular task types depending on the industry concerned. Steps are: 1) Identify task steps where errors may result in accidents; 2) Specify the nature of the error; 3) Identify possible recovery; 4) Recommend preventative measures. Errors of several types are analysed: Planning Errors, Action Errors, Checking Errors, Retrieval Errors, Information Communication Errors, Selection Errors.       | Equivalent to Human HAZOP.  |                         |   |   | 3 |   |   |   | 6 |         |             |        |        |        |        |            |  |  | <ul style="list-style-type: none"> <li>• [Kirwan, Part 1, 1998]</li> </ul>   |
| 593. | PHECA<br>(Potential Human Error Causes Analysis)                      | Tab    | HRA              | 1988                | PHECA is a computerised system based on the identification of error causes, which interact with performance shaping factors. It has a wider application than just error identification (e.g. potential error reduction strategies). Like HAZOP it uses guidewords to identify hazards.  | Apparently not in current use or else used rarely.  |                         |   |   | 3 |   |   |   | 6 |         |             |        |        |        |        |            |  |  | <ul style="list-style-type: none"> <li>• [Kirwan, Part 1, 1998]</li> <li>• [PROMA15, 2001]</li> </ul>  |
| 594. | PHI<br>(Preliminary Hazard Identification)                            | Gen    | Hzi              | 1991<br>or<br>older | Reduced version of PHA, only containing a column with hazards. The results are recorded in the Preliminary Hazard List (PHL). Is sometimes considered a generic term rather than a specific technique.  | Performed in the early stages of lifecycle.   |                         |   |   | 3 |   |   |   |   |         |             |        |        |        |        |            |  |  | <ul style="list-style-type: none"> <li>• [MUFTIS3.2-I, 1996]</li> <li>• [Storey, 1996]</li> </ul>  |

| 595. | PHL<br>(Preliminary Hazard List)                   | Tab    | Hzi          | 1989<br>or<br>older | Is an initial analysis effort within system safety. Lists of initial hazards or potential accidents are identified during concept development. The PHL may also identify hazards that require special safety design emphasis or hazardous areas where in-depth safety analyses are needed as well as the scope of those analyses. At a minimum, the PHL should identify: The Hazard; When identified (phase of system life cycle); How identified (analysis, malfunction, failure) and by whom; Severity and Probability of Occurrence; Probable/actual cause(s); Proposed elimination/mitigation techniques; Status (Open-action pending /Closed-eliminated/Mitigated; Process of elimination/mitigation; Oversight/approval authority. | Usually the results are fed into a PHA.  |                         |   | 3 |   |   |   |   |   |         |                     | (aircraft) | x      | x      |        |            |  | <ul style="list-style-type: none"> <li>• [FAA AC431]</li> <li>• [FAA00]</li> <li>• [ΣΣ93, ΣΣ97]</li> </ul> |
| 596. | PHRA<br>(Probabilistic Human Reliability Analysis) | Int    | HRA<br>, Par | 1990                | Time-related method. A distinction is made between routine operation and operation after the event. Error probabilities are calculated for identified classes of routine operation with the help of simple evaluation instructions. Simulator experiments can be performed to evaluate the reliability of human actions after trouble has materialised. Various time-reliability curves for varying the complex trouble situations are determined from the experiments. Error probabilities are determined from the time-reliability curves.   | Developed by EDF (Electricité de France). Update of HCR (Human Cognitive Reliability), in which advantages of HCR have been used and in which it was tried to eliminate the disadvantages. |                         |   |   |   | 5 |   |   |   |         | nuclear             |            |        | x      |        |            | <ul style="list-style-type: none"> <li>• [Straeter, 2000]</li> <li>• [Straeter, 2001]</li> </ul> |  |

| 599. | PPAS<br>(Professional Performance Analysis System)                               | Tab    | HRA<br>, Ret | 1977 | Main purpose is providing remedies to minimize pilot error and optimize pilot performance. The five interactive factors of the model include knowledge, skills, attitudes, systems environment, and obstacles. Four analysis steps: 1) Describe the process, function, task, error, or low performance, in order to see if the pilot was aware of risks, threats and consequences of their actions and if there was stimulus that degraded this awareness. 2) Assess the impact of the error on this particular accident or incident by determining whether removal would have prevented the accident. 3) Assess the visibility of the error to the crew members. 4) Analyze a detailed flow chart to see if the crew had adequate knowledge to cope with the errors and anomalies that occurred. Other questions are explored to determine deficiencies. Recommendations are given for each of the situations where a problem was perceived. | Four levels of learning are examined. These include unconsciously incompetent (crew is unaware that they don't know something), consciously incompetent (the crew is aware that they don't know something), consciously competent (the crew has knowledge and skill but must apply great effort to accomplish it), and unconsciously competent (the crew has over learned the knowledge or skill and can apply it without conscious thought). |                         |   |   |   |   |   |   |   |         |                       |        |        |        |        |            |  | <ul style="list-style-type: none"> <li>• [Besco, 2005]</li> <li>• [Wiegman et al, 2000]</li> </ul>  |  |
| 600. | PRA<br>(Probabilistic Risk Assessment based on FTA/ETA)                          | Int    | HZA          | 1965 | Quantified probabilistic analysis of low probability, high severity events. Evaluates the risks involved in the operation of a safety critical system. The risk assessment forms the basis of design decisions. It uses techniques like FMEA, FTA, Event Tree Analysis (ETA), Event Sequence Diagrams (ESD), Master Logic Diagrams (MLD), Reliability Block Diagrams (RBD), etc. to quantify risk.  | Initially nuclear power industry, now any system with catastrophic accident potential. Useful before major design decisions. Not reasonable for the minor system aspects. Tools available, e.g. WinNUPRA, see [GAIN AFSA, 2003]. Alternative names are Probabilistic Hazard Analysis, PSA (Probabilistic Safety Assessment), QSA (Quantitative Safety Assessment).  |                         |   |   | 3 | 4 | 5 |   |   |         |                       |        |        |        |        |            |  | <ul style="list-style-type: none"> <li>• [NASA PRA, 2011]</li> <li>• [Bishop, 1990]</li> <li>• [FAA00]</li> <li>• [Kirwan, 1994]</li> <li>• [MUFTIS3.2-I, 1996]</li> <li>• [ΣΣ93, ΣΣ97]</li> <li>• [Statematelatos]</li> <li>• [GAIN AFSA, 2003]</li> <li>• [Storey, 1996]</li> </ul> |  |
| 601. | PRASM<br>(Predictive Risk Assessment and Safety Management)                      | Int    | Mit          | 2000 | Methodology for incorporating human and organisational factors in the risk evaluation and safety management in industrial systems. The methodology includes the cost-benefit analysis of the risk control measures and options to enable elaborating a rational risk control strategy for implementing more effective safety related undertakings in different time horizons.   |   |                         |   |   |   | 4 | 5 | 6 |   | 8       | no-domain-found       |        |        |        |        |            |  |   | <ul style="list-style-type: none"> <li>• [Kosmowski, 2000]</li> </ul>      |
| 602. | PREDICT<br>(Procedure to Review and Evaluate Dependency In Complex Technologies) | Tab    | HZA          | 1992 | Is targeted at the relatively unpredictable or bizarre event sequences that characterise events, in that such events are incredible or not predictable until accidents give us 20:20 hindsight. The method utilises a group to identify errors, and is thus HAZOP-based, with keyword systems, followed by three categories of assumption-testing keywords. The technique essentially allows the analyst to test the assumptions underpinning the design and safety cases for plants. The method allows inserting a keyword randomly to enable the analyst to consider more 'lateral' possible causal connections.  | PREDICT differs from HAZOP in that it directs the analysis both inside and outside the process and places greater emphasis on identifying ways in which latent failures may reveal themselves.  |                         |   |   | 3 | 4 |   | 6 |   |         | nuclear,<br>(oil&gas) | x      |        |        |        |            |  |   | <ul style="list-style-type: none"> <li>• [Kirwan, Part 1, 1998]</li> </ul> |

| 606. | PRMA<br>(Procedure Response Matrix Approach)                    | Tab    | Hzi     | 1994 | Aim is to identify errors of commission (EOC), which are more closely linked to cognitive errors (global and local misdiagnoses), and slip-based EOCs during emergencies. PRMA to some extent represents a more sophisticated and detailed investigation than the FSMA, though one that is more resource-intensive. The approach has several major stages: develop a PRM for all initiating events that produce significantly different plant responses; for each PRM review the decision points in the procedural pathway; identify potential incorrect decisions resulting from misinterpretation or failure of the plant to provide the appropriate information, or due to a procedural omission (lapse).  | Related to SHERPA and SCHEMA and TEACHER-SIERRA. The approach has strong affinities with FSMA, which has faults on one axis of its matrix and symptoms on the other one. The technique is useful for considering how system status indications and procedures will affect performance in abnormal or emergency events, such as a nuclear power plant emergency scenario requiring diagnosis and recovery actions using emergency procedures. As such, it can be used to evaluate alarm system design adequacy, for example. |                         |   | 3 | 5 |   |   |   |   |         | (nuclear)                         | x      |        |        | x      |            |   | <ul style="list-style-type: none"> <li>• [Kirwan, Part 1, 1998]</li> </ul>  |

| 615. | PSSA (Preliminary System Safety Assessment) according to EATMP SAM | Int    | OpR       | 2002 | The PSSA according to EATMP SAM determines that the proposed system architecture is expected to achieve the safety objectives. PSSA examines the proposed system architecture and determines how faults of system elements and/or external events could cause or contribute to the hazards and their effects identified in the FHA. Next, it supports the selection and validation of mitigation means that can be devised to eliminate, reduce or control the hazards and their end effects. System Safety Requirements are derived from Safety Objectives; they specify the potential means identified to prevent or to reduce hazards and their end effects to an acceptable level in combination with specific possible constraints or measures. Five substeps are identified: 1) PSSA initiation; 2) PSSA planning; 3) Safety requirements specification; 4a) PSSA validation; 4b) PSSA verification; 4c) PSSA assurance process; 5) PSSA completion. Most of these steps consist of subtasks. | This PSSA is a refinement and extension of JAR-25 steps and of the PSSA according to ARP 4761, but its scope is extended to Air Navigation Systems, covering AIS (Aeronautical Information Services), SAR (Search and Rescue) and ATM (Air Traffic Management).   | 1                       |   |   |   | 4 | 5 | 6 |   |         |             |                                 | ATM    | x      | x      | x          | x |  | <ul style="list-style-type: none"> <li>• [EHQ-SAM, 2002]</li> <li>• [Review of SAM techniques, 2004]</li> </ul> |
| 616. | PTHA (Probabilistic Tsunami Hazard Assessment)                     | Step   | HZA       | 2014 | PTHA is a tsunami hazard assessment approach based on the Monte Carlo approach to probabilistic seismic hazard assessment (PSHA) and adapted to tsunami. The aim of a PTHA is to calculate the probability of exceeding a set of tsunami heights at the coast or near shore. The PTHA can be performed using an empirical and numerical method, and applies statistical analysis of historical tsunami data. The result is a tsunami hazard curve that determines a tsunami return period for a target coastal area or a target nuclear power plant site.   | Approach should be followed by a tsunami fragility assessment that evaluates a failure probability of safety-related equipment and structures caused by the force and inundation height of a tsunami wave, and by a system analysis that calculates the risk caused by a tsunami using event trees and fault trees. |                         |   |   |   |   | 5 |   |   |         |             | nuclear, environment            | x      |        |        |            |   | <ul style="list-style-type: none"> <li>• [Gibbons et al, 2020]</li> <li>• [Horspool et al, 2014]</li> </ul>  |   |
| 617. | PTS (Predetermined Time Standards)                                 | Gen    | HFA, Par  | 1948 | PTS are internationally recognised time standards used for work measurement. They are employed to estimate performance times for tasks that can be decomposed into smaller units for which execution times can be determined or estimated. The time necessary to accomplish these fundamental motions should be constants.  | Also referred to as Predetermined Motion Time System (PMTS). Several PTS exist, including MTM, MOST, MODAPTS, GSD, SeqEasy, TMU, MTS.   |                         |   |   |   |   | 5 |   |   |         |             | navy, manufacturing, healthcare |        |        | x      |            |   | <ul style="list-style-type: none"> <li>• [MIL-HDBK, 1999]</li> </ul>   |   |
| 618. | PUEA (Predictive Use Error Analysis)                               | Tab    | HRA, Task | 2007 | Proactive analytical method for use error analysis. Is a further development of the methods Action Error Analysis (AEA), Systematic Human Error Reduction and Prediction Approach (SHERPA) and Predictive Human Error Analysis (PHEA). PUEA employs a process for breaking down the user's tasks into steps and then identifying and investigating potential errors of use for each step. Makes use of two question levels: one applied to tasks/functions, and the second to operations. It builds on human cognition theory. The results of the analysis are presented in matrixes showing which tasks have the most serious consequences, which error types gives rise to the highest risk, in which tasks there are errors difficult to detect, etc.  | Aims at analysis of medical equipment designs. See also AEA, SHERPA, PHEA.  |                         |   | 3 |   | 5 |   |   |   |         |             | healthcare, road, leisure       | x      |        | x      |            |   | <ul style="list-style-type: none"> <li>• [Bligard &amp; Osvalder, 2014]</li> <li>• [Sekar Fadlilah et al, 2019]</li> <li>• [Lundgren et al, 2011]</li> <li>• [Bligard &amp; Osvalder, 2007]</li> </ul> |   |

| 619. | PUMA<br>(Performance and Usability Modelling in ATM) | Int    | Task    | 1995 about | PUMA is a toolset designed to enable the prediction and description of controller workload for ATC scenarios. It is capable of assessing the effect on controller workload of various computer assistance tools. PUMA uses observational task analysis to try to capture all the relevant information about cognitive activities in a task, usually based on video analysis of someone (i.e. an ATCO) performing the task. Each task or activity is then classified by a PUMA analyst and its impact on workload calculated as a function of its usage of cognitive resources, and as a function of other activities' (competing) resource requirements. Some tasks or activities will conflict more with each other as they are demanding the same cognitive resources, as defined in a 'conflict matrix' within PUMA. Central to the PUMA methodology is a workload prediction algorithm, which calculates how different task types will impact on workload alone, and together. This algorithm is based on the Wickens (1992) multiple resource theory. The output is a prediction of MWL (Mental Workload) as it changes throughout the overall task. | The PUMA Toolset was developed for NATS by Roke Manor Research Limited. PUMA has been applied to a number of future operational concepts, providing useful information in terms of their likely workload impacts, and potential improvements in the designs of future tools for the ATCO. The motivation for using PUMA stems from the fact that real time simulation is resource intensive, requiring a lot of manpower to plan, prepare for, conduct, analyse and report each trial. It is therefore useful to apply the PUMA 'coarse filter' to new operational concepts before expensive real time simulation. This allows the more promising and the less promising options to be identified, before proceeding with the better options, to full simulation. |                         | 2 |   |   | 5 |   |   |   |         |             | ATM    |        |        | x      |            |   |  | <ul style="list-style-type: none"> <li>• [Kirwan et al, 1997]</li> <li>• [GAIN ATM, 2003]</li> <li>• [FAA HFW]</li> </ul> |
| 620. | Pure Hazard Brainstorming                            | Tab    | Hzi     | 1996       | Hazard identification through "pure" brainstorming with experts, generally along scenarios. Allows identification of many hazards that are unimaginable for some other approaches. Rule 1: no analysis during the session and no solving of hazards; Rule 2: criticism is forbidden; Rule 3: use a small group; Rule 4: brainstormers should not be involved in the operation's development; need to play devil's advocates; current expertise is better than past experience; Rule 5: moderator should watch the basic rules; should make the brainstorm as productive as possible; needs to steer the hazard identification subtly; write short notes on flip-over or via beamer; Rule 6: short sessions and many coffee breaks and...bottles of wine for the most creative hazard; the last hazard; and inspiration, if necessary...   | Also referred to as Scenario-based Hazard brainstorming or TOPAZ-based hazard brainstorming.  |                         |   | 3 |   |   |   |   |   |         | ATM         | x      | x      | x      | x      | x          | <ul style="list-style-type: none"> <li>• [DeJong, 2004]</li> <li>• [DeJong et al, 2007]</li> <li>• [DeJong et al, 2007a]</li> </ul> |  |   |

| 621. | Q850<br>(CAN/CSA-Q850<br>Risk Management<br>Guideline for<br>Decision-Makers) | Int    | OpR,<br>Dec | 1997                | Q850 is a guidance for risk management steps, intended to assist decision-makers in managing risk issues, including injury or damage to health, property, the environment, or something else of value. The process consists of six steps which are typically followed in several iterations: 1) Initiation – define the problem and scope and assemble the risk management team; 2) Preliminary analysis – identify hazards, start risk information library; 3) Risk estimation – estimate frequency and consequences of risk scenarios; 4) Risk evaluation – Estimate and integrate benefits and costs and assess stakeholder acceptance of risk; 5) Risk control – identify feasible risk control options and evaluate them; 6) Action/monitoring – develop implementation plan, evaluate effectiveness of risk management decision process, establish monitoring process. Complementary to all steps is Risk communication. | Q850 has been approved as a National Standard of Canada by the Standards Council of Canada. The guidelines do not provide specific technical tools for risk analysis, evaluation, and control | 1                       | 2 | 3 | 4 | 5 | 6 | 7 | 8  | maritime,<br>environment,<br>chemical | x           | x      | x      | x      | x   | • [CSA Q850.97, 2002] |

| 629. | RAIT (Railway Accident Investigation Tool) | Step     | Ret     | 1993          | Tool developed to investigate accidents by identifying contributions to and aggregate Railway Problem Factors, i.e. representative of significant organisational and managerial root causes of railway infrastructure accidents. RAIT starts with the accident outcome and then traces back to the active and latent failures that originated higher up within the organisation.   | Developed for use at British rail by James Reason and others. Also used as basis for training courses. MAIT (Marine Accident Investigation Tool) is a derived version for Marine safety.  |                         |   |   |   |   |   |   |   |         | 8           | <u>rail</u>       | x      | x      | x      | x          | x |  |  | <ul style="list-style-type: none"> <li>[PROMAI5, 2001]</li> <li>[RAIT slides]</li> <li>[Reason et al, 1994]</li> </ul>        |
| 630. | RAM (Resilience Analysis Matrix)           | Stat     | Ret     | 2013          | Aims to analyse resilience characteristics with a focus on functions and on paths/instantiations. RAM matrix has rows and columns labelled by functions. Element (k,m) contains the input from function m to function k (k not equal to m) and (k,k) contains the output of function k. Rows and columns are ordered such that rows for functions are placed below all functions that they receive inputs from. If there are feedback loops, these are visible above the diagonal; otherwise the area above the diagonal is empty. Next, lines are drawn through all functions that are involved in an instantiation (set of couplings among functions for specified time intervals) of the function network. Visual inspection enables analysing upstream and downstream interactions, and differences and similarities between instantiations. | Can be used with SADT/IDEF0 or with FRAM. RAM can be used for retrospective (reconstructing the actual instantiations of an event) as well as prospective (possible instantiations in future behaviour of the system) analysis. |                         |   |   | 4 |   |   |   |   |         |             | aviation, defence |        |        |        |            | x |  |  | <ul style="list-style-type: none"> <li>[Lundberg &amp; Woltjer, 2013]</li> </ul>  |

| 634. | RASRAM<br>(Reduced Aircraft Separation Risk Assessment Model) | Int    | Col     | 1997 | RASRAM is used for quantitative assessment of the increase in risk of aircraft operations due to reduced separation requirements, and/or reduced risk due to new surveillance or navigational technology. It is a PC-based tool that is based on a large database of aircraft data, incorporating aircraft and air traffic controller data. The overall organisation of RASRAM is a fault-tree analysis of the major failure modes in specific operational scenarios. The approach includes time-budget analyses of dynamic interactions among multiple participants in a scenario, each with defined roles, responsibilities, information sources, and performance functions. Examples are response times for pilots and air traffic controllers. The methodology works directly with the functional form of probability distributions, rather than relying on Monte Carlo simulation techniques. The probability of a Near Mid-Air Collision (NMAC) is computed, and from this, the probability of a collision, using a factor of collisions/NMAC. Probability distributions of lateral miss distance and simultaneous runway occupancy are also computed. | RASRAM was developed by Rannoch Corporation.  |                         |   |   | 3 | 4 | 5 |   |   |         |             |        | (ATM)  | x      |        |            |  | x |  | <ul style="list-style-type: none"> <li>• [GAIN ATM, 2003]</li> <li>• [Sheperd, 1997]</li> </ul> |
| 635. | RAT<br>(Risk Analysis Tool)                                   | Tab    | Ret     | 2009 | The RAT aims to analyse a reported incident event in order to understand the factors involved, to place the event in context with other events, to identify risk elements, and to prioritise actions designed to reduce the effect of those risk elements. The RAT uses a marksheet system in which a user can give scores to determine the severity of the occurrence and the probability that a similar occurrence will recur in the future. There are separate marksheets for encounters between multiple aircraft, between two aircraft under tower control, between an aircraft and a vehicle on the ground, and for a situation where one aircraft is making a level bust or an airspace infringement, and for a situation with an ATM technical problem.  | Developed by Eurocontrol. The FAA has adopted the tool under the name RAP (Risk Analysis Process), and uses it to assess the risk of Risk Analysis Events (RAEs), which are given events in which two airborne aircraft came closer than 66% of the radar separation minimum. |                         |   |   |   | 5 |   |   |   |         |             | ATM    | x      | x      | x      | x          |  |   | <ul style="list-style-type: none"> <li>• [RAT Guidance, 2009]</li> <li>• [ATO SMS Manual v3.0]</li> <li>• [GAO, 2011]</li> <li>• [Licu et al, 2011]</li> </ul> |   |

| 637. | RBD (Reliability Block Diagrams) | Stat   | Mod      | 1972         | <p>Technique related to FTA where one is looking for a success path instead of failure path. Aim is to model, in a diagrammatical form, the set of events that must take place and conditions which must be fulfilled for a successful operation of a system or task. An RBD is drawn as a series of blocks connected in parallel or series configuration. Each block represents a component of the system with a failure rate. If a path may be found through the network from beginning to end, the system still works. An RBD may be converted to a success tree by replacing series paths with AND gates and parallel paths with OR gates. A success tree may then be converted to a fault tree by applying de Morgan's theorem.</p>  | <p>Alternative name: SDM (Success Diagram Method). Useful for the analysis of systems with relatively straightforward logic, but inferior to fault tree analysis for more complex systems. In some references referred to as Dependence Diagrams (DD). RBD is also sometimes referred to as equivalent to a Fault Tree without repeated events. Tools available, but tools for FTA may also be useful.</p> |                         |   |   |   | 4 |   |   |   |         |             | aircraft, energy, oil&gas, food | x  |        |        |            |  |  | • [Bishop, 1990]<br>• [EN 50128, 1996]<br>• [FT handbook, 2002]<br>• [MUFTIS3.2-I, 1996]<br>• [Sparkman, 1992] |             |

| 638. | RBRT<br>(Risk Based Resource Targeting)            | Step   | Dec      | 2007 | RBRT is a structured process designed to support aircraft certification oversight in determining risk, assigning resources based on that risk, and providing options to mitigate risk through targeted application of resources. A technical specialist answers RBRT questions about the applicant's organization and their experience with similar products or modifications. Next, RBRT assigns weights to the indicator questions associated with probability of noncompliance. These weights are combined with a severity rating based on the criticality of the product or modification to arrive at a composite risk value (CRV) for the project. RBRT's assessment tool also provides a 'group risk score' (low, medium, or high) for each technical discipline (electrical, mechanical, propulsion, etc).  | In an audit report at <a href="http://www.oig.dot.gov/library-item/5591">http://www.oig.dot.gov/library-item/5591</a> it is argued that RBRT needs to be improved (e.g. it is stated to underestimate risk and be subjective).  |                         |   |   |   |   | 5 | 6 |   |         |  | aircraft | x      | x      |        |            |  | <ul style="list-style-type: none"> <li>• [Notice IR N 8110.100]</li> <li>• [DoT AV-2011-136, 2011]</li> <li>• [Order IR 8110.102]</li> <li>• [FAA RBRT slides]</li> </ul> |
| 639. | RCA<br>(Root Cause Analysis)                       | Step   | Org, Ret | 1955 | This method identifies causal factors to accident or near-miss incidents. The technique goes beyond the direct causes to identify fundamental reasons for the fault or failure; it asks why things happen, instead of treating the symptoms. It is a systematic process of gathering and ordering all relevant data about counter-quality within an organisation; then identifying the internal causes that have generated or allowed the problem; then analysing for decision-makers the comparative benefits and cost-effectiveness of all available prevention options. To accomplish this, the analysis methodology provides visibility of all causes, an understanding of the nature of the causal systems they form, a way to measure and compare the causal systems, an understanding of the principles that govern those causal systems, and a visibility of all internal opportunities for the organisation to control the systems. | The root cause is underlying contributing causes for observed deficiencies that should be documented in the findings of an investigation. Several training courses, tools and supporting packages are (commercially) available. |                         |   |   |   |   |   |   |   | 8       | healthcare, nuclear, chemical,oil&gas, aviation, ATM, rail | x        |        | x      | x      | x          | <ul style="list-style-type: none"> <li>• [FAA00]</li> <li>• Several Internet sources</li> <li>• [ΣΣ93, ΣΣ97]</li> <li>• [Browne et al, 2008]</li> </ul>                                  |   |
| 640. | RCFF<br>(Regulatory-based Causal Factor Framework) | Tab    | HZA      | 2009 | The RCFF is a system safety process for analyzing hazards and associated causal factors due to introducing new technology into NAS (U.S. National Airspace System). It provides a qualitative means of identifying and assessing hazards controlled by existing regulations. The process starts at Part level of the current regulatory framework. Parts are associated with functions, which are intended to provide a contextual backdrop for the regulations. The functions are then associated with hazards. Finally, causal factors and their linkages associated with the hazards are identified using a text mining tool. The linkages are envisioned as the illustration of the influence or of the conditional dependency between two nodes constituting a network structure.   | Has been applied to the introduction of unmanned aerial systems into manned airspace.   |                         |   | 3 | 4 | 5 |   |   |   |         | aviation, aircraft   | x        |        |        | x      |            | <ul style="list-style-type: none"> <li>• [FAA UAS SMS]</li> <li>• [FAA UAS SMS slides]</li> <li>• [FAA RCFF results]</li> <li>• [FAA RCFF approach]</li> <li>• [Oztekin 2009]</li> </ul> |   |

| 641. | RCM (Reliability Centered Maintenance)        | Step   | HwD, Des | 1978          | RCM is the concept of developing a maintenance scheme based on the reliability of the various components of the system or product in question. Aims to anticipate the times when the system is down for maintenance, and to schedule other activities or processes accordingly. Seven steps: 1) Selection of equipment for RCM analysis; 2) Define the boundaries and function of the systems that contain the selected equipment; 3) Define the failure modes of the system; 4) Identify the root causes of the failure modes; 5) Assess the effects of failure; 6) Select a maintenance tactic for each failure mode; 7) Implement and then regularly review the maintenance tactic that is selected. | Approach varies between industries, but usually relies on FMECA. RCM is defined in the standard SAE JA1011, Evaluation Criteria for Reliability-Centered Maintenance (RCM) Processes. See also FMECA.                   |                         | 2 | 3 |   | 5 | 6 |   |   |                        | aircraft, defence, nuclear, leisure, navy, maritime, chemical, oil&gas, manufacturing, healthcare, food, rail | x      |        | x      |        |            |  | <ul style="list-style-type: none"> <li>[Cotaina et al, 2000]</li> <li>[Moubray, 2000]</li> <li>[NASA-RCM]</li> <li>[Relax-RCM]</li> <li>[Nowlan &amp; Heap, 1978]</li> <li>[Rausand &amp; Vatn, 1998]</li> <li>[Cotaina et al., 2000]</li> </ul> |
| 642. | RCS (Risk Classification Schemes)             | Tab    | Dec      | 1977 or older | These are matrices that relate the severity of risk or hazard to its maximum tolerated probability.   | These exist for different domains and different types of systems, see the references for a collection. In many industries used to define a Safety Integrity Level. See also Safety Targets Setting.                     | 1                       |   |   |   |   |   |   |   |                        | ATM, management, healthcare, finance, food  | x      |        |        |        |            |  | <ul style="list-style-type: none"> <li>[Storey, 1996]</li> </ul>   |

| 646. | RECUPERARE  | Step   | Ret      | 2000   | Model based on systematic analysis of events including Human Reliability in Nuclear Plants. Model puts emphasis on the recovery process during events and uses a classification for the default-recovery links and delays for detection diagnosis and actions. The method aims at the following objectives: 1) Identify the main mechanisms and parameters which characterise events occurring in the French PWSs (power series solution) during one year; 2) Provide a way of classifying deficiencies and associated recoveries; 3) Provide a way of classifying events according to previous parameters; 4) Record these data in a base to make trend analyses.   | Developed by IRSN (Institute for Radiological Protection and Nuclear safety) for operating experience feedback analysis. For the time being, IRSN emphasises the difficulty in connecting performance indicators to safety. Has also been adapted for healthcare domain, in a version called RECUPERARE-Health.  |                         |   |   | 3 |   |   | 5 |   |         | 7           |                            | nuclear, healthcare |        |        |            | x |   |   | <ul style="list-style-type: none"> <li>• [Matahri, 2002]</li> <li>• [Matahri, 2003]</li> <li>• [Straeter, 2001]</li> </ul>   |
| 647. | REDA (Ramp Error Decision Aid)                    | Int    | Ret      | 1999 ? | The REDA process focuses on a cognitive approach to understand how and why the event occurred, not who was responsible. REDA contains many analysis elements that enable the user to conduct an in-depth investigation, summarise findings and integrate them across various events. The REDA data organisation enables operators to track their progress in addressing the issues revealed by the analyses. REDA is made up of two components: the interview process and contributing factors analysis. It consists of a sequence of steps that identify key contributing factors to ramp crew errors and the development of effective recommendations aimed at the elimination of similar errors in the future.    | Developed by Boeing. REDA is based on MEDA. REDA is designed to investigate incidents that occurred during the receiving, unloading, loading, servicing, maintaining, and dispatching of commercial aircraft at an airport.  |                         |   |   |   |   |   |   |   |         | 8           | airport                    |                     |        |        |            |   | x | x | <ul style="list-style-type: none"> <li>• [GAIN AFSA, 2003]</li> <li>• [Reda example]</li> <li>• [Balk &amp; Bossenbroek, 2010]</li> <li>• [REDA User Guide]</li> </ul> |
| 648. | Redundancy for Fault Detection                    | Gen    | Des      | 1980 ? | By employing redundancy, checks may be made for differences between units to determine sub-system failures.  | Useful in safety computer applications.  |                         |   |   |   |   |   |   |   | 6       |             | software                   | x                   |        |        |            |   |   |   | <ul style="list-style-type: none"> <li>• [Bishop, 1990]</li> </ul>   |
| 649. | Refined Reich collision risk model                | Math   | Col      | 1993   | Refinement of Reich collision risk model (CRM) to evaluate risk of collision between aircraft. Replaces the two restrictive Reich assumptions by one less restrictive one.   |  |                         |   |   |   |   |   | 5 |   |         |             | (ATM)                      |                     |        |        |            |   | x |   | <ul style="list-style-type: none"> <li>• [Bakker &amp; Blom, 1993]</li> <li>• [Mizumachi &amp; Ohmura, 1977]</li> <li>• [MUFTIS3.2-II, 1996]</li> </ul>                |
| 650. | REHMS-D (Reliable Human Machine System Developer) | Int    | Des, Mit | 1995   | REHMS-D uses a six-stage system engineering process, a cognitive model of the human, and operational sequence diagrams (OSD) to assist the designer in developing human-machine interfaces subject to top-level reliability or yield requirements. Through its system engineering process, REHMS-D guides the designer through the understanding of customer requirements, the definition of the system, the allocation of human functions, the basic design of human functions, the assignment of job aids, and the design of tests to verify that the human functions meet the allocated reliability requirements. REHMS-D can be used for both the synthesis of new systems and the analysis of existing systems. | REHMS-D is called a major advance in system and reliability engineering that has broad application to systems and processes. It can be used to synthesise or analyse radar and sonar systems, control rooms and control systems, communications systems, geographic information systems, manufacturing processes, maintenance processes, biomedical systems, transportation systems, and other systems and processes that involve human-computer interfaces. |                         | 2 |   |   |   |   |   | 6 |         |             | (defence), (manufacturing) | x                   |        |        |            |   |   |   | <ul style="list-style-type: none"> <li>• [MIL-HDBK, 1999]</li> <li>• [FAA HFW]</li> <li>• [LaSala, 2003]</li> <li>• [Alley, 2005]</li> </ul>                           |

| 651. | Reich Collision Risk Model                        | Math   | Col          | 1964 | This model estimates the probability of a mid-air collision between two en route level flying aircraft. The main objective is the determination of sufficiently safe lateral separation between adjacent parallel routes or vertical separation between adjacent flight levels. Important assumptions are that there are no collision avoidance manoeuvres, there is independence of position and velocity, and deviations from track in the lateral and vertical dimensions are independent of time. The model is primarily applicable to procedurally controlled oceanic traffic.   | Developed by UK Royal Aircraft Establishment.  |                         |   |   |   |   | 5 |   |   |         |             |         | ATM  |        |        |            | x |   | <ul style="list-style-type: none"> <li>[Reich, 1964]</li> <li>[ICAO-CIR319, 2009]</li> <li>[Bakker &amp; Blom, 1993]</li> <li>[Brooker, 2002]</li> <li>[MUFTIS3.2-II, 1996]</li> <li>[ICAO Doc 9574]</li> <li>[Endoh, 1982]</li> </ul> |
| 652. | Relative Ranking                                  | Step   | HwD<br>, Mit | 1971 | Rank hazardous attributes (risk) of process. Hazards can be ranked based on e.g. frequency of occurrence or on severity of consequences, etc. The ranking may lead to prioritisation of mitigating measures.  | Versions of this method were developed by Fine and by Kinney & Wiruth (Naval weapons center, California). Applicable to any system wherein a ranking approach exists or can be constructed. See also PC (Paired Comparisons). See also Rapid Risk Ranking. |                         |   |   |   |   | 5 |   |   |         |             |         | navy, ergonomics, management, healthcare, energy | x      |        |            |   |   | <ul style="list-style-type: none"> <li>[ΣΣ93, ΣΣ97]</li> <li>[Kinney &amp; Wiruth, 1976]</li> </ul>  |

| 655. | REPA<br>(Risk and<br>Emergency<br>Preparedness<br>Analysis) | Int    | OpR     | 1993                | Aim is to get a total overview of the risks involved for concept selection and to check compliance with acceptance criteria. REPA consists of two parts: risk analysis, and emergency-preparedness analysis. The risk analysis involves four activities: 1) System description; 2) Identification of hazards and listing of initial events; 3) Accident modelling, consequence evaluation and assessment of probabilities; 4) Evaluation of risk and comparison with risk-acceptance criteria. The emergency-preparedness analysis identifies dimensioning accidental events, i.e. major accidents which generate the most severe accidental loads that the safety barriers must be able to withstand. |   |                         |   | 2 | 3 | 4 | 5 |   |   |   | oil&gas     | x      |        |        |        | x          |  | • [Kjellen, 2000] |
| 656. | Requirements<br>Criticality Analysis                        | Step   | Mit     | 1996<br>or<br>older | The requirements of the software/ hardware system are analysed and those are identified that could present catastrophic or critical hazards. Identified potential hazards are then addressed by adding or changing the system requirements and reflowing them to hardware, software and operations as appropriate. Safety critical requirements are placed into a tracking system to ensure traceability of software requirements throughout the software development cycle from the highest level specification all the way to the code and test documentation.   |   |                         |   |   | 3 |   |   |   |   | software,<br>(avionics),<br>(nuclear),<br>(space) |             | x      |        |        |        |            | • [FAA00]<br>• [NASA-GB-1740.13-96]  |                   |
| 657. | Re-try Fault<br>Recovery                                    | Gen    | Mit     | 1990<br>or<br>older | Aim is to attempt functional recovery from a detected fault condition by re-try mechanisms, i.e. re-executing the same code or by re-booting. There are three general categories of methods used to recover to a previous state: (1) checkpointing, (2) audit trails, and (3) recovery cache.  | Should be used with care and always with full consideration of the effect on time-critical events, and the effect of lost data during re-boot. Combine with software time-out checks or watchdog timers. Software architecture phase. |                         |   |   |   |   |   | 6 |   | software  |             | x      |        |        |        |            | • [Bishop, 1990]<br>• [EN 50128, 1996]<br>• [Rakowsky]<br>• [Sparkman, 1992] |                   |
| 658. | Return to Manual<br>Operation                               | Gen    | Des     | 1990<br>or<br>older | Aim is to provide the operator or supervisor the information and the means to perform the function of the failed automatic control system.   | Useful provided it is used with care.   |                         |   |   |   |   |   | 6 |   | electronics                                       | x           |        |        |        |        |            | • [Bishop, 1990]   |                   |
| 659. | RFA<br>(Repetitive Failure<br>Analysis)                     | Step   | HZA     | 1991<br>or<br>older | Aim is to model recurring events that prevent a technical system from performing its function. It provides a systematic approach to address, evaluate and correct repetitive failures, such as Repeated failure of a piece of equipment; Repeated failure of items belonging to a system or subsystem; Failures of the same/similar parts in various different equipment or systems.   | Applicable in maintenance, e.g. in an RCM process.  |                         |   |   | 4 |   |   | 6 |   | nuclear,<br>manufacturing,<br>oil&gas             | x           |        |        |        |        |            | • [ΣΣ93, ΣΣ97]   |                   |
| 660. | RHA<br>(Requirements<br>Hazard Analysis)                    | Step   | Mit     | 1995<br>or<br>older | The purpose of RHA is to perform and document the safety design requirements/design criteria for a technical system or facility undergoing development or modification, and to develop safety requirements from regulations, standards, laws, etc. that are generic and not related to a specific identified hazard.   | RHA is typically executed after concept exploration and as input to preliminary design. According to [Ericson, 2005] this is an alternative name for SRCA.  |                         |   |   | 3 |   |   |   |   | (aircraft),<br>(navy)                             | x           | x      |        |        |        |            | • [FAA00]<br>• [AF SSH, 2000]<br>• [Ericson, 2005]                           |                   |

| 661. | RIF diagram (Risk Influencing Factor Diagram) or RIA (Risk Influence Analysis) | Stat   | Mod     | 1998          | RIFs are classified according to Operational RIFs, Organisational RIFs and Regulatory related RIFs. The Operational RIFs are divided into technical, human and external factors. The RIFs are next arranged in an (Accident) Frequency Influence Diagram and an (Accident) Consequence Influence Diagram. All RIFs are characterized by their status (present state) and their effect (influence) on other RIFs. Arrows indicate the influence between one RIF and another, usually at the next upward level.  | Alternative to fault trees and event trees. A RIF is a set of relatively stable conditions influencing the risk. It is not an event, and it is not a state that fluctuates over time. RIFs are thus conditions that may be influenced or improved by specific actions. Also referred to as Influence Diagrams.  |                         |   |   |   |   | 5 |   |   |         |   | aviation, rail, oil&gas | x      |        | x      |            |   |   | <ul style="list-style-type: none"> <li>[Vinnem, 2000]</li> <li>[Hokstad et al, 1999]</li> <li>[Albrechtsen &amp; Hokstad, 2003]</li> </ul> |
| 662. | Risk Decomposition   | Math   | Mod     | 1996          | The aim of this technique is to mathematically decompose the frequency of occurrence of a rare event into a product of frequencies and conditional frequencies of less rare events. This is to be done in such a way that the decomposition is mathematically sound, and the evaluation of the factors in the product is less demanding than the evaluation of the rare event itself.  | An example rare event evaluated using this technique is the collision between two aircraft. The factors in the product are to be evaluated using other methods such as Monte Carlo simulation of a stochastic dynamic risk model. Developed as part of TOPAZ.   |                         |   |   |   | 4 |   |   |   |         |   | ATM                     |        |        |        | x          |   | <ul style="list-style-type: none"> <li>[Blom &amp; Bakker et al, 2003]</li> <li>[MUFTIS3.2-II, 1996]</li> </ul> |  |
| 663. | Risk Graph Method  | Stat   | HZA     | 1994          | Risk Graphs are used to determine safety integrity levels (SIL) using process risk factors or parameters for hazardous events. Usually, four parameters are employed: consequence (C), frequency and exposure time (F), probability of avoiding the hazardous event (P), and probability of the unwanted occurrence (W). The four factors are evaluated from the point of view of a theoretical person being in the incident impact zone. The likelihood and consequence are determined by considering the independent protection layers during the assessment. Once these factors are determined, the risk graph is utilized to determine a SIL that will reduce the risk to a tolerable level. | Developed by IEC 61508. Reference [ACM, 2006] lists some advantages and disadvantages. A Safety Integrity Level (SIL) is a numerical target for the probability of failure of a Safety Instrumented Function (SIF), which is a set of actions to protect against a single specific hazard. Risk Graphs are mainly popular in Europe; In the US, Layers of Protection Analysis (LOPA) is a more popular alternative to determine SILs. |                         |   |   |   | 5 |   |   |   |         | electronics, chemical, nuclear                  | x                       |        |        |        |            | <ul style="list-style-type: none"> <li>[Gulland, 2004]</li> <li>[IEC 61508, 1998]</li> <li>[ACM, 2006]</li> <li>[Summers, 1998]</li> <li>[Risk Graph Example]</li> </ul>  |   |  |
| 664. | Risk-Based Decision Analysis   | Gen    | Dec     | 1983 or older | Risk-Based Decision Analysis aims at quantifying, and taking into account, the actual costs, benefits and risks associated with the decision-making process, regarding alternative policies. The assessed probability of policy failure, e.g. resulting from stochastic simulation of environmental systems under study, forms useful information in this decision-making.   | Risk-Based Decision Analysis is commonly regarded as a generic term; many different techniques can be used in the analysis. It is of particular use in cases where information relative to a specific state of an activity may be insufficient and/or inadequate.   |                         |   |   | 4 | 5 | 6 |   |   |         | environment, management, food, nuclear, finance | x                       |        |        |        |            | <ul style="list-style-type: none"> <li>[Mylopoulos &amp; Mylopoulos, 1999]</li> <li>[Faber &amp; Stewart, 2003]</li> <li>[Evans et al, 1993]</li> <li>[ARES-RBDA]</li> <li>[FAA00]</li> <li>[ΣΣ93, ΣΣ97]</li> </ul> |   |  |

| 674. | SADA<br>(Safety Architectural Design Analysis)                                  | Step   | SwD       | 1996 or older | Analysis performed on the high-level design to verify the correct incorporation of safety requirements and to analyse the Safety-Critical Computer Software Components (SCCSCs). It uses input from the Architectural Design, the results of the Software Safety Requirements Analysis (SSRA), and the system hazard analyses. The SADA examines these inputs to: a) Identify as SCCSCs those software components that implement the software safety requirements identified by the SSRA. Those software components that are found to affect the output of SCCSCs shall also be identified as SCCSCs; b) Ensure the correctness and completeness of the architectural design as related to the software safety requirements and safety-related design recommendations; c) Provide safety-related recommendations for the detailed design; d) Ensure test coverage of the software safety requirements and provide recommendations for test procedures. The output of the SADA is used as input to follow-on software safety analyses. | In [FAA00] referred to as ADA (Architectural Design Analysis).   |                         |   |   |   |   |   |   |   |         |             |        |        |        |        |            |  | <ul style="list-style-type: none"> <li>• [FAA00]</li> <li>• [NASA-STD-8719]</li> <li>• [Rakowsky]</li> </ul>  |
| 675. | SADT<br>(Structured Analysis and Design Technique)                              | Stat   | Dec, Task | 1973          | SADT aim is to model and identify, in a diagrammatical form using information flows, the decision making processes and the management tasks associated with a complex system. A SADT model is an organised sequence of diagrams, each with supporting text. SADT also defines the personnel roles in a software project. Main boxes contain the name of the process/action. On the left hand side of a box, incoming arrows model inputs of the action. On the upper part, incoming arrows model data necessary for the action. On the bottom, incoming arrows model the means used for the action. On the right hand side, outgoing arrows model the outputs of the action.  | Developed by Douglas T. Ross and SofTech, Inc. between 1969-1973. Good analysis tool for existing systems, and can also be used in the design specification of systems. Software requirements specification phase and design & development phase. SADT also defines the personnel roles in a software project. The military equivalent to SADT is IDEF0. |                         | 2 |   |   |   |   |   |   |         |             |        |        |        |        |            |  | <ul style="list-style-type: none"> <li>• [Bishop, 1990]</li> <li>• [EN 50128, 1996]</li> <li>• [HEAT overview]</li> <li>• [Rakowsky]</li> <li>• [Beevis, 1992]</li> </ul> |

| 677. | SAFER<br>(Safety Assessment For Explosives Risk) | Math   | OpR           | 2000          | SAFER was developed to provide a more comprehensive assessment of the overall risk of explosives operations. It calculates risk in terms of the statistical expectation for loss of life from an explosives event. Three components are multiplied to estimate annual maximum probability of fatality, P(f), and the expected fatalities, E(f): (1) the probability of an explosives event, P(e), (2) the probability of a fatality given an event, P(f/e), and (3) the average exposure of an individual, E(p). SAFER calculates risk using the following basic equations: $P(f) = P(e) \times P(f/e) \times E(p)$ to determine individual risk; $E(f) = \Sigma(P(e) \times P(f/e) \times E(p))$ to determine group risk. Risk exceeding individual and group risk limits constitutes a violation of the risk acceptance criteria. | Developed for DDESB (Department of Defense Explosives Safety Board), and for Defence application only. See also Explosives Safety Analysis. | 678. | Safety Bag                                       | Step   | Mit           | 1969 ?        | Aim is to protect against residual specification and implementation faults in software that adversely affect safety. In this technique, an external monitor, called a safety bag, is implemented on an independent computer using a different specification. The primary function of the safety bag is to ensure that the main system performs safe - but not necessarily correct - operations. The safety bag continually monitors the main system to prevent it from entering an unsafe state. If a hazardous state does occur, the system is brought back to a safe state by either the safety bag or the main system.   | May be considered for fail-systems, provided there is adequate confidence in the dependability of the safety bag itself. Tools are not applicable. Software architecture phase. The Safety Bag is a form of Fault Detection and Diagnosis (FDD). |                         |   |   | 3 |   |   | 6 |   |         |             | space, electronics   | x       | x      |        |            |   |  | • [Bishop, 1990]<br>• [EN 50128, 1996]<br>• [Sparkman, 1992] |                 |
| 679. | Safety Monitoring                                | Step   | Hzi           | 1992 or older | Safety monitoring is a means of protecting against specific failure conditions by directly monitoring a function for failures that would contribute to the failure condition. Monitoring functions may be implemented in hardware, software, or a combination of hardware and software. Through the use of monitoring technique, the software level of the monitored function may be reduced to the level associated with the loss of its related system function.  |  |                         |   |   |   |   |   |   | 7 |         |             | aircraft, software, healthcare   | x       | x      |        |            |   |  | • [DO-178B, 1992]  |                 |
| 680. | Safety Review or Safety Audit                    | Gen    | Hzi, Val, Ret |               | A Safety Review assesses a system, identifies facility conditions, or evaluates operator procedures for hazards in design, the operations, or the associated maintenance.   | Periodic inspections of a system, operation, procedure, or process are a valuable way to determine their safety integrity. A Safety Review might be conducted after a significant or catastrophic event has occurred.                            |                         |   |   |   |   |   |   | 7 |         |             | road, rail, manufacturing, healthcare, nuclear, chemical, aviation, aircraft, software |         |        |        |            | x |  | • [FAA00]<br>• [Storey, 1996]<br>• [ΣΣ93, ΣΣ97]              |                 |

| 681. | Safety Scanning  | Tab    | Org.<br>Dec | 2010          | Safety Scanning aims at scanning a given operational change on all aspects important for safety. These aspects are referred to as "Safety Fundamentals", and they are divided into Safety Regulatory aspects, Safety Management aspects, Operational Safety aspects, and Safety Architecture aspects. Application of the method results in addressing key issues that need to be part of a consistent safety argument, which should provide the basis for regulatory acceptance of an operational change.  | Developed for Eurocontrol SRC (Safety Regulatory Commission) by University of Kassel, National Aerospace Laboratory NLR and Helios Ltd. Was built on 'Safety Screening Techniques', but with more focus on Regulatory Safety issues. The method is supported by the Safety Scanning Tool (SST) which is an electronic wizard implemented in MS Excel that asks up to 5 questions per Safety Fundamental. The method can be used in all lifecycle stages of a proposed change, but is most effective during earlier stages. | 1                       | 2 |   |   |   |   |   |   |         |             |        | 8      | aviation, ATM, airport  | x      | x          | x | x | x | <ul style="list-style-type: none"> <li>• [SCAN TF, 2010]</li> <li>• [SCAN TF, 2010a]</li> <li>• [SCAN TF, 2010b]</li> </ul>                       |
| 682. | Safety Screening Techniques                            | Step   | OpR         | 2006          | Collection of four methods of screening Air Traffic Management (ATM) system changes, built upon the rationale of the "Safety Fundamentals", in order to make a preliminary assessment of their safety implications, and also to enable systematic consideration of safety issues within ATM strategy development. The objectives of the methods are: <ul style="list-style-type: none"> <li>• To anticipate safety issues at an early stage in ATM concept development, including both positive and negative effects on safety.</li> <li>• To prioritise ATM changes for more detailed safety assessment studies.</li> <li>• To enable systematic consideration of safety issues within ATM strategy development.</li> </ul> | The four methods have been proposed by four groups of experts, from Eurocontrol, NLR (National Aerospace Laboratory), DNV (Det Norske Veritas), TÜV (Technischer Überwachungsverein). Successor tool is named SST (Safety Scanning Tool), see at Safety Scanning.  |                         | 2 |   |   |   | 5 |   |   |         |             |        |        | (ATM)   | x      |            | x | x |   | <ul style="list-style-type: none"> <li>• [Straeter, 2006]</li> </ul>  |

| 685. | SAFSIM<br>(Simulations for Safety Insights)                                 | RTS    | HRA     | 2002                | SAFSIM is a process and a toolbox of measures. The process involves either the measurement of the safety of air traffic controller performance when faced with specific safety-related events (e.g. hazards) in a real-time human-in-the-loop simulation, or else general safety monitoring using less intrusive procedures to see if any safety-relevant information arises during a real time simulation.  | Launched by EEC (Eurocontrol Experimental Centre) in 2002.  |                         |   |   | 3 |   | 5 |   |   |         |             |        |        |        |        |            |  | <ul style="list-style-type: none"> <li>[SAFSIM guidance]</li> <li>[Scaife, 2000]</li> <li>[Gordon, 2004]</li> <li>[Shorrock et al, 2005]</li> <li>[Gizdavu02]</li> <li>[SAP15]</li> </ul>  |
| 686. | SAGAT<br>(Situation Awareness Global Assessment Technique)                  | Tab    | HFA     | 1988                | SAGAT is a specialised questionnaire for querying subjects about their knowledge of the environment. This knowledge can be at several levels of cognition, from the most basic of facts to complicated predictions of future states. It is administered within the context of high fidelity and medium fidelity part-task simulations, and requires freezing the simulation at random times.   | Developed by Mica Endsley. SAGAT is a method that provides an objective measure of situation awareness (SA) during a simulated operation. It is not intended for use during an actual operation.  |                         |   |   |   |   |   |   |   | 7       |             |        |        |        |        |            |  | <ul style="list-style-type: none"> <li>[Endsley, 1997]</li> <li>[HIFA Data]</li> <li>[MIL-HDBK, 1999]</li> <li>[FAA HFW]</li> <li>[GAIN ATM, 2003]</li> <li>[Alley, 2005]</li> </ul>   |
| 687. | SAI DCT<br>(Safety Attribute Inspection Data Collection Tool)               | Dat    | Dat     | 1999<br>or<br>older | This tool is used to collect data about regulatory compliance in order to assess the adequacy of the design of the processes associated with each system element for an air carrier. The tool is organized in accordance with six safety attributes, i.e. qualities of a system, (e.g., authority, responsibility, procedures, controls, process measurements, and interfaces) that should be present in well-designed air carrier systems and processes.  | Inspectors use the Safety Attribute Inspection questions to collect data for design assessment. Air carrier applicants use SAI DCTs during initial certification to document the results of their self audit.   |                         |   | 2 |   |   |   |   |   | 7       |             |        |        |        |        |            |  | <ul style="list-style-type: none"> <li>[FAA FSIMS, 2009]</li> <li>[SAI-AQP, 2008]</li> <li>[GAO, 1999]</li> </ul>  |
| 688. | SAINT<br>(Systems Analysis of Integrated Network of Tasks)                  | FTS    | Task    | 1974                | SAINT is a general purpose network modelling and simulation technique that can be used in the design and development of complex human-machine systems. Using a Monte Carlo approach, SAINT provides the conceptual framework and the means for modelling systems whose processes can be described by discrete and continuous functions/tasks, and interactions between them. It provides a mechanism for combining human performance models and dynamic system behaviours in a single modelling structure.   | Micro-SAINT (1985) is a commercial version of SAINT. It is easier to use than SAINT but has fewer features. It is a discrete-event task network modelling tool that can be used to analyse and improve any system that can be described by a flow diagram. It can be used to answer questions about the costs of alternative training, about how crew workload levels or reaction times affect system performance, and about the allocation of functions between people and machines. |                         |   | 2 |   |   |   |   |   |         |             |        |        |        |        |            |  | <ul style="list-style-type: none"> <li>[CBSSE90, p40]</li> <li>[HEAT overview]</li> <li>[Kirwan, 1994]</li> <li>[Kirwan, Part 1, 1998]</li> <li>[THEMES, 2001]</li> <li>[GAIN ATM, 2003]</li> <li>[Pritsker et al., 1974]</li> <li>[Beevis, 1992]</li> <li>[Morrison, 2003]</li> </ul> |
| 689. | SALIENT<br>(Situational Awareness Linked Indicators Adapted to Novel Tasks) | Tab    | HFA     | 1993                | SALIENT involves the use of a theoretically based list of behaviours to assess team behavior. It is an inferential technique that requires experts to rate situation awareness (SA) based upon implicit evidence from observable correlates. SALIENT comprises 5 phases: Phase 1: Delineation of behaviours theoretically linked to team SA. Phase 2: Development of scenario events to provide opportunities to demonstrate team SA behaviours. Phase 3: Identification of specific, observable responses. Phase 4: Development of script. Phase 5: Development of structured observation form. | Developed by the US Naval Air Warfare Centre.   |                         |   |   |   | 4 | 5 |   |   |         |             |        |        |        |        |            |  | <ul style="list-style-type: none"> <li>[Muniz et al, 1998]</li> <li>[Smith et al, 2007]</li> <li>[FAA HFW]</li> <li>[Muniz et al., 1993]</li> </ul>  |

| 690. | SAME<br>(Safety Assessment Made Easier)                                | Int    | OpR     | 2008          | SAME describes the broad framework on to which the EATMP SAM-defined processes, and the associated safety, human-factors and system-engineering methods, tools and techniques, are mapped in order to explain their purpose and interrelationships. Where EATMP SAM focuses on the negative contribution to risk, SAME additionally considers the positive contribution of the concept under investigation to aviation safety. It does this by proposing a 'broader approach to safety assessment', consisting of complementary success and failure approaches: The success approach seeks to show that an ATM system will be acceptably safe in the absence of failure; The failure approach seeks to show that an ATM system will still be acceptably safe, taking into account the possibility of (infrequent) failure. In SAME, the safety assessment is driven by a safety argument structured according to system assurance objectives and activities. | SAME was developed by EUROCONTROL. | 691. | SAMPLE<br>(Situation Awareness Model for Pilot-in-the-Loop Evaluation) | FTS    | HFA     | 1996          | SAMPLE models the situation awareness and actions of operators (individuals or crews) of complex human-machine systems. Recent variants have been applied to the study of the effects of individual differences and environmental stressors on cognitive performance. SAMPLE assumes that the actions of an operator are guided by highly structured standard procedures and driven by detected events and assessed situations. Some variants assume a multitasking environment. In all cases, the operator (or crew) is concerned primarily with performing situation assessment, continuous control and communication, and discrete procedure execution.   | Developed by G.L. Zacharias and K.A. Harper, Charles River Analytics. It has been applied to e.g. combat aviation, commercial aviation and air traffic control, battlefield command and control, and Military Operations on Urban Terrain (MOUT). |                         |   |   | 4 | 5 |   |   |   |         | aviation, ATM, defence, nuclear, police |        |        | x      |        |            |  |  | <ul style="list-style-type: none"> <li>• [GAIN ATM, 2003]</li> <li>• [FAA HFW]</li> <li>• [Parasuraman &amp; Rovira, 2005]</li> <li>• [Zacharias et al, 1995]</li> <li>• [Morrison, 2003]</li> </ul> |   |
| 692. | SAR<br>(Safety Action Record)  | Tab    | Val     | 2000 or older | A SAR is a unique record used to document a hazard in a hazard tracking system. Each SAR includes: A description of the hazard, status; An updated narrative history, including origin and context of hazard identification; A current risk assessment; Justification for the risk severity and probability to include existing controls, and requirements for the SRVT (Safety Requirements Verification Table); A mitigation and verification plan; Potential effects if the hazard is realized. Each SAR must be classified according to status (Proposed, Open, Monitor, Recommend closure, Closed). All program SARs are reviewed with (1) Proposed status, (2) Open status, and (3) current high risk. This review is to occur at least biannually per program. The key is the maintenance and accessibility of a SAR.   | See also HTRR and SRMTS.  |                         |   |   |   |   | 6 | 7 |   |         | (aircraft), (ATM)                       | x      | x      |        |        |            |  |  | <ul style="list-style-type: none"> <li>• [SAP15]</li> <li>• [FAA00] section 2.2.3</li> <li>• [SRM Guidance, 2007]</li> </ul>   |   |

| 693. | SARA<br>(Small Airplane Risk Assessment)                               | Math   | HwD      | 2000 | In this method, one first determines the Safety Effect (i.e. the potential outcome of the known failure condition, being catastrophic, hazardous, major or minor effect) and the Safety Risk Factor (i.e. Safety Effect (a) x Operational Use (b) x Percentage used by population (c) + Number of Occurrences (d) + Events versus Population (e) + Time between Events (f) + Aircraft Type (g)). Each of (a) though (g) is translated to a number between -3 and +4. The higher the Safety Effect and the higher the Safety Risk Factor, the more negative the airworthiness effect. The results are plotted on an Initial Risk Assessment Evaluation Chart (Safety effect on y-axis, Safety Risk Factor on x-axis). From the chart, the most likely responsive action is determined, ranging from providing service information (lower left corner), to emergency action (upper right corner). | SARA is also referred to as “14 CFR Part 23 (AD) Risk Assessment” or “Risk Assessment for Airworthiness Concerns on Small Airplane Directorate Products”. The term ‘Small Airplane’ refers to airplanes in a range from manned balloons, gliders, and turbine engine airplanes to commuter category airplanes.   |                         |   |   |   |   |   | 5 | 6 |         |             |        |        |        |        |            |  |  | <ul style="list-style-type: none"> <li>• [SADAD Manual]</li> <li>• [FAA AC 23-11B]</li> </ul>  |
| 694. | SARD<br>(Strategic Assessment of ATM Research and Development results) | Step   | Val      | 2008 | SARD defines a process and a set of ‘transition criteria’ for the analysis of ATM R&D (air traffic management research and development) results per operational concept from a strategic view point. The process assesses the maturity of operational concepts, in terms of the phases of the Concept Lifecycle Model of E-OCVM, and provides recommendations for next steps.   | The SARD process has been successfully applied and further improved through application to two ATM operational concepts. In principle it can be used for any ATM improvement under development. See also E-OCVM.   |                         |   |   |   |   |   |   | 6 |         |             |        |        |        |        |            |  |  | <ul style="list-style-type: none"> <li>• [CAATS II D13, 2009]</li> </ul>   |
| 695. | SART<br>(Situation Awareness Rating Technique)                         | Tab?   | Mod<br>? | 1989 | SART is a multi-dimensional rating scale for operators to report their perceived situational awareness. It examines the key areas of SA: understanding, supply and demand. These areas are further broken down into the 14 dimensions ([Uhlarik & Comerford, 2002] mentions 10 dimensions). From the ratings given on each of the dimensions situational awareness is calculated by using the equation $SA = U - (D - S)$ where U is summed understanding, D is summed demand and S is summed supply.   | Developed by R.M. Taylor in 1989. SART is simple, quick and easy to apply. It has been applied to several complex domains, including air traffic control. 3D-SART is a narrowed-down version of SART, applicable to aircrew, and covering only 3 dimensions: (a) Demands on Attentional Resources - a combination of Instability of Situation, Complexity of Situation, and Variability of Situation; (b) Supply of Attentional Resources - a combination of Arousal of Situation, Concentration of Attention, Division of Attention, and Spare Mental Capacity; and (c) Understanding of Situation - a combination of Information Quantity, Information Quality, and Familiarity. See also Rating Scales. |                         |   |   |   |   | 5 |   |   |         |             |        |        |        |        |            |  |  | <ul style="list-style-type: none"> <li>• [MIL-HDBK, 1999]</li> <li>• [Uhlarik &amp; Comerford, 2002]</li> <li>• [FAA HFW]</li> <li>• [Taylor, 1990]</li> <li>• [GAIN ATM, 2003]</li> </ul> |

| 696. | SAS (Safety Assessment Screening)                              | Tab    | Val       | 2010 or older | SAS is a form that is used to document the FAA ARP (Airport operations) Safety Assessment process. It is used to document the appropriate level of assessment, the steps of safety risk management and the final signatures and approvals, hence it documents the evidence to support whether a proposed action is acceptable from a safety risk perspective. There are three versions of the SAS: one each for Projects, Modification of standards, and Advisory circular standards.  | [Order 5200.11] provides a SAS form.  |                         |   |   |   |   |   |   |   |         | 7           |        | (airport) | x      |        |            |  |  |   | <ul style="list-style-type: none"> <li>[ARP SMSs, 2011]</li> <li>[Order 5200.11]</li> <li>[ARP SMS Guide, 2011]</li> </ul> |
| 697. | SA-SWORD (Situational Awareness Subjective Workload Dominance) | Tab    | Task      | 1989          | SA-SWORD is a Situation Awareness adaptation of SWORD, which measures workload of different tasks as a series of relative subjective judgments compared to each other. SWORD has three steps: 1. Collect subjective between-tasks comparative ratings using a structured evaluation form after the subject has finished all the tasks; 2. Construct a judgment matrix based on the subjective ratings; 3. Calculate the relative ratings for each task.  | See also Paired Comparisons.  |                         |   |   |   |   |   |   |   |         | 5           |        | aviation  |        |        | x          |  |  |   | <ul style="list-style-type: none"> <li>[Vidulich et al, 1991]</li> <li>[Snow &amp; French, 2002]</li> </ul>                |
|      | SAT Diagram (Sequence and Timing Diagram)                      |        |           |               |  | See OSD (Operational Sequence Diagram)  |                         |   |   |   |   |   |   |   |         |             |        |           |        |        |            |  |  |   |  |
| 698. | SATORI (Systematic Air Traffic Operations Research Initiative) | Dat    | Dat, Trai | 1993          | Incident reporting system. Goal is to gain a better understanding of the interaction between the various elements of displayed information, verbal interactions, and the control actions taken by air traffic control specialists. SATORI enables its users to re-create segments of operational traffic in a format similar to what was displayed to the ATCS, for example, showing relative location and separation, speeds, and headings of aircraft. SATORI can display data blocks, beacon targets, and conflict alerts. Video and audio are synchronized, and the air traffic situation can be displayed in four dimensions. | Developed by FAA Civil Aerospace Medical Institute (CAMI). Is used, for example, to review training management issues, investigate accidents and operational errors, develop facility specific specialty training programs, and present facility-wide briefings on operational incidents. |                         |   |   |   |   |   |   |   |         |             | 8      | ATM       | x      |        | x          |  |  |   | <ul style="list-style-type: none"> <li>[Pounds, 2003]</li> <li>[FAA HFW]</li> </ul>  |
| 699. | SAVANT (Situation Awareness Verification and Analysis Tool)    | Tab    | HFA       | 2000          | SAVANT is a combination of SAGAT and SPAM, implemented in software. The SAVANT measure is an attempt to retain and combine the advantages of both techniques. The specific advantages to be retained from SAGAT are: (1) queries are anchored in the airspace (i.e. the location of aircraft on the sector map); (2) the controller enters responses directly into the system. From SPAM the specific advantages to be retained are: (1) no interruption of the simulation, (2) no extensive use of memory, (3) queries of relational information instead of verbatim information.   | SAVANT was developed by the FAA Technical Center in New Jersey, USA. It is applied during a simulated operation.  |                         |   |   |   |   |   |   |   |         | 7           | ATM    |           |        | x      |            |  |  | <ul style="list-style-type: none"> <li>[FAA HFW]</li> <li>[Willems &amp; Heiney, 2002]</li> </ul> |  |

| 700. | SCA (Sneak Circuit Analysis)                  | Stat   | Hzi     | 1967          | SCA aims to identify sneak (or hidden) paths in electronic circuits and electro-mechanical systems that may cause unwanted action or inhibit desired functions. It is based on identification of designed-in inadvertent modes of operation rather than on failed equipment or software. Sneak conditions are classified into: 1. Sneak paths - unintended electrical paths within a circuit and its external interfaces. 2. Sneak timing—unexpected interruption or enabling of a signal due to switch circuit timing problems. 3. Sneak indications—undesired activation or deactivation of an indicator. 4. Sneak labels—incorrect or ambiguous labelling of a switch. | This technique is applicable to control and energy-delivery circuits of all kinds, whether electronic/ electrical, pneumatic, or hydraulic. Tools available. Originally developed by Boeing for NASA Apollo Program to look at unintended connections in wiring systems. [Hahn et al., 1991] present an adaptation that considers errors of commission in HRA. Highly resource-intensive. |                         |   | 2 | 3 | 4 |   |   |   |         |             |        |        | x      | x      | x          |   |   |  | <ul style="list-style-type: none"> <li>• [Boeing, 1970]</li> <li>• [Bishop, 1990]</li> <li>• [EN 50128, 1996]</li> <li>• [FAA AC431]</li> <li>• [FAA00]</li> <li>• [Kirwan, 1995]</li> <li>• [Kirwan, Part 1, 1998]</li> <li>• [Rakowsky]</li> <li>• [ΣΣ93, ΣΣ97]</li> <li>• [Sparkman, 1992]</li> <li>• [Ericson, 2005]</li> <li>• [Hahn et al., 1991]</li> <li>• [Miller, 1989]</li> </ul> |  |
| 701. | SCART (Safety Culture Assessment Review Team) | Tab    | Org     | 2008          | Aim is safety culture assessment by means of questions in five groups: 1. Safety value, 2. Safety leadership. 3. Safety accountability. 4. Integration of safety into activities. 5. Safety learning.   |   |                         |   |   |   |   |   |   |   |         |             |        |        |        |        |            |   | x |  | <ul style="list-style-type: none"> <li>• [Mkrtchyan &amp; Turcanu, 2012]</li> </ul>  |  |
| 702. | SCDM (Safety Case Development Manual)         | Int    | OpR     | 2003 and 2006 | The Safety Case Development Manual gives an overview of a methodology being proposed for the construction and development of Safety Cases. The manual includes the concept of a Safety Case as presenting the entirety of argument and evidence needed to satisfy oneself and the regulator with respect to safety. It does not provide guidance on the generation or documentation of the evidence itself.   | Developed by Eurocontrol. Version 2.2 (dated 2006) is a complete rewrite of Version 1.3 which was published in 2003, taking into consideration user needs and recent experience with Safety Case developments.  | 1                       |   |   |   |   |   |   |   |         |             |        |        |        |        |            |   | x |  | <ul style="list-style-type: none"> <li>• [SCDM, 2006]</li> </ul>   |  |
| 703. | Scenario Analysis                             | Step   | OpR     | 1979 or older | Scenario Analysis identifies and corrects hazardous situations by postulating accident scenarios where credible and physically logical. Scenario analysis relies on the asking “what if” at key phases of flight and listing the appropriate responses. Steps are: 1) Hypothesize the scenario; 2) Identify the associated hazards; 3) Estimate the credible worst case harm that can occur; 4) Estimate the likelihood of the hypothesized scenario occurring at the level of harm (severity).   | Scenarios provide a conduit for brainstorming or to test a theory in where actual implementation could have catastrophic results. Where system features are novel, subsequently, no historical data is available for guidance or comparison, a Scenario Analysis may provide insight.   |                         |   | 3 | 5 |   |   |   |   |         |             |        |        | x      |        |            |   | x |  | <ul style="list-style-type: none"> <li>• [FAA00]</li> <li>• [ΣΣ93, ΣΣ97]</li> </ul>  |  |
| 704. | Scenario Process Tool                         | Step   | Hzi     | 2000 or older | The Scenario Process tool aims at identifying unusual hazards by visualizing them. The flow of events established in an analysis of the operation considered is used as a guide. The user of the tool next attempts to visualize the flow of events in an operation by constructing a “mental movie”. The flow of events can also be visualised twice. The first time, the user sees the events as they are intended to flow. The next time, the user injects “Murphy” at every possible turn. As hazards are visualized, they are recorded for further action.   | Also referred to as 'the mental movie tool'. The tool is especially useful in connecting individual hazards into situations that might actually occur. Similar to What-If Analysis.   |                         |   | 3 |   |   |   |   |   |         |             |        |        | x      | x      | x          | x |   |  | <ul style="list-style-type: none"> <li>• [FAA00]</li> </ul>  |  |

| 711. | SDA<br>(Sequence<br>Dependency<br>Analysis)                         | Stat   | Task        | 1999<br>or<br>older | SDA follows from TLA and notes the dependency between different task elements. It can also estimate the qualitative uncertainty in time estimates for each sub-task, and the timing data source used. SDA is useful in identifying tasks whose reliability is critical, and therefore tasks that require a high quality of human factors design. SDA can therefore lead to error reduction recommendations (often via the TTA and Ergonomics Review) that will have a general effect on human reliability across a scenario or several scenarios. SDA also helps to identify the longest time likely for the task sequence, and where it may perhaps be best to gain more accurate time estimates to ensure the TLA is accurate.   |  |                         |   | 2 | 3 |   |   |   | 6 |         |             | nuclear |        |        | x      |            |  |  | • [Kirwan & Kennedy & Hamblen]  |
| 712. | SDAT<br>(Sector Design<br>Analysis Tool)                            | FTS    | Hzi,<br>HRA | 1990                | SDAT supports nearly all airspace and traffic data sources used within the FAA and overlays the traffic data on the airspace environment. The user is able to select from menus the portions of the data to display and how the data are displayed. SDAT permits the user to postulate changes in the airspace and/or traffic data to compare the analysis results to those with the original. SDAT analysis tools include measures of traffic loadings within control sectors or within a given radius of a specified fix. SDAT also performs a calculation of the expected number of ATC aircraft separations per hour in each airspace sector. This allows the user to see in advance how a proposed change could impact controller task load, particularly separation assurance task load, and possibly prevent errors resulting from excessive demands on the controllers' attention. | SDAT concept start was in 1985; it came in full operation in 1990. Developed by Washington Consulting Group.   |                         |   |   |   |   |   | 5 |   |         | ATM         |         |        |        | x      | x          |  |  | • [GAIN ATM, 2003]<br>• [FAA HFW]   |
| 713. | SDCPN<br>(Stochastically and<br>Dynamically<br>Coloured Petri Nets) | Dyn    | Mod         | 2006                | SDCPN is an extension of DCPN (Dynamically Coloured Petri Nets), in the sense of allowing token colours that stochastically evolve, while the powerful mathematical properties of DCPN are retained.   | SDCPN are mathematically equivalent to HSMP (Hybrid State Markov Processes). DCPN and SDCPN are the main modelling formats used for MA-DRM. See also MA-DRM, see also TOPAZ, see also DCPN.  |                         |   |   |   | 4 | 5 |   |   |         | ATM         | x       | x      | x      | x      | x          |  |  | • [Everdij & Blom, 2006]<br>• [Everdij et al, 2006]<br>• [Everdij & Blom, 2008]<br>• [Everdij & Blom, 2010]<br>• [Everdij & Blom, 2010a]<br>• [Everdij, 2010] |
| 714. | SDFG<br>(Synchronous Data<br>Flow Graphs)                           | Stat   | Mod         | 1988<br>or<br>older | An SDFG is a graph with 'actors' as vertices and 'channels' as edges. Actors represent basic parts of an application which need to be executed. Channels represent data dependencies between actors. Streaming applications essentially continue their execution indefinitely. Therefore, one of the key properties of an SDFG which models such an application is liveness, i.e., whether all actors can run infinitely often.  | SDFG is a data flow model of computation that is traditionally used in the domain of Digital Signal Processing platforms. Possible approach for the implementation of concurrent real-time control systems. Tools available. Relation with Petri Nets. |                         | 2 |   |   |   |   |   |   |         | software    |         | x      |        |        |            |  |  | • [Bishop, 1990]<br>• [Ghamarian, 2008]<br>• [Pullaguntla, 2008]  |

| 715. | SDHA<br>(Scenario-Driven Hazard Analysis)   | Step   | OpR     | 2005 | The SDHA is used to understand the dynamics of an accident. The first step involves the generation of possible scenarios. This includes scenario description, initial contributors, subsequent contributors, life-cycle phase, possible effect, system state and exposure, recommendations, precautions and controls. Next, hazards are classified and communicated. Hazard “counts” are obtained, which lead to implicit proportions or percentages of the hazard system and subsystem sources as derived from the scenarios.  | Developed by Raheja and Allocco (2005), building on an approach by Hammer (1972).  |                         |   |   | 4 |   |   |   |   |         |             |          | (aviation)  |        |        |            | x |  |  | <ul style="list-style-type: none"> <li>• [Oztekin, 2007]</li> <li>• [Luxhoj, 2009]</li> </ul> |
| 716. | SDL<br>(Specification and Description Language)   | Int    | Des     | 1976 | Aims to be a standard language for the specification and design of telecommunication switching systems. SDL is an object-oriented, formal language defined by The International Telecommunications Union–Telecommunications Standardisation Sector (ITU–T) as recommendation Z.100. The language is intended for the specification of complex, event-driven, real-time, and interactive applications involving many concurrent activities that communicate using discrete signals.  | Based on Extended FSM, similar to SOM. Tools available. Software requirements specification phase and design & development phase.  |                         | 2 |   |   |   |   |   |   |         |             |          | electronics | x      | x      |            |   |  | <ul style="list-style-type: none"> <li>• [Bishop, 1990]</li> <li>• [EN 50128, 1996]</li> </ul>                               |   |

| 719. | Secondary Task Monitoring              | Step     | Task      | 1986 or older | Secondary task monitoring is a method of measuring mental workload in which the operator is required to perform two tasks concurrently—the primary task of interest and another (related or unrelated) task. The operator’s performance on the secondary task is used to estimate primary task workload. The method of secondary task monitoring is an important tool to help the human error practitioner assess mental workload so that especially stressful tasks can be identified and redesigned or re-allocated.  | See also MRT (Multiple Resource Theory).   |                         |   |   |   |   |   |   |   |         |             |        |        |        |        |            |  |  | <ul style="list-style-type: none"> <li>[FAA HFW]</li> <li>[MIL-HDBK, 1999]</li> </ul>   |
| 720. | SEEA (Software Error Effects Analysis) | Tab      | SwD       | 1973          | SEEA aims to identify critical software modules, and to detect software errors and their consequences.  | Qualitative Design tool. Similar to SFMEA (Software FMEA). Software architecture phase.  |                         |   |   | 3 |   |   |   |   |         |             |        |        |        |        |            |  |  | <ul style="list-style-type: none"> <li>[Fragola&amp;Spahn, 1973]</li> <li>[EN 50128, 1996]</li> <li>[Lutz &amp; Woodhouse, 1996]</li> <li>[Rakowsky]</li> </ul> |
| 721. | Seismic Analysis                       | Step     | Mit       | 1927          | Seismic Analysis is a structural analysis technique that involves the calculation of the response of a building (or nonbuilding) structure to earthquakes. Aim is to ensure that structures and equipment resist failure in seismic events.   | Physical structures and equipment.   |                         |   |   |   |   |   | 6 |   |         |             |        |        |        |        |            |  |  | <ul style="list-style-type: none"> <li>[ΣΣ93, ΣΣ97]</li> </ul>  |
| 722. | Self testing and Capability testing    | Step     | SwD       | 1978 or older | Software Testing technique. Aim is to verify online that the system maintains its capability to act in the correct and specified manner.  | Essential on a normally dormant primary safety system. See also Software Testing.  |                         |   |   |   |   |   | 6 |   |         |             |        |        |        |        |            |  |  | <ul style="list-style-type: none"> <li>[Bishop, 1990]</li> </ul>  |
| 723. | Self-Reporting Logs                    | Gen, Dat | Dat, Task | 1998 or older | Self-reporting logs are paper-and-pencil journals in which users are requested to log their actions and observations while interacting with a product.  | Alternative name: Diary Method. See also Journalled Sessions.  |                         |   | 2 |   |   |   |   |   |         |             |        |        |        |        |            |  |  | <ul style="list-style-type: none"> <li>[FAA HFW]</li> </ul>   |
| 724. | SEM (Safety Element Method)            | Tab      | Org       | 1997          | SEM is an assessment and development tool for improvement of the safety, health and environment (SHE) management, tailored for application in the Norwegian mining industry. The method identifies the current SHE performance and the desired future of the organisation. The tool also gives aid to find improvement measures. SEM emphasises consensus decisions through internal group discussions. The method is designed as a matrix, where the columns represent five phases of development. The rows define the safety elements considered. The content is divided in six main elements that ought to be considered by the organisation; Goals/ambitions, Management, Feedback systems/learning, Safety culture, Documentation and Result Indicators. | Method is tailored for application in the Norwegian mining industry. Development of the tool has been carried out through a structured group problem solving process. The participants were resource persons representing different parties in the industry. |                         |   |   |   |   | 5 | 6 |   |         |             |        |        |        |        |            |  |  | <ul style="list-style-type: none"> <li>[Kjellen, 2000]</li> <li>[Alteren &amp; Hovden, 1997]</li> </ul>   |

| 726. | Sensitivity Analysis | Gen, Math | Val     |      | Sensitivity Analysis is a term representing a variety of techniques that study how the variation (uncertainty) in the output of a mathematical model can be apportioned, qualitatively or quantitatively, to different sources of variation in the input of the model. The analysis systematical changes values for parameters in a model to determine the effects of such changes.   | Many techniques exist to determine the sensitivity of the output with respect to variation in the input, such as linearisation, sampling, variance based methods, Monte Carlo methods. See also What-If Analysis. See also B&UA (Bias and Uncertainty Assessment). See also Uncertainty Analysis. |                         |   |   |   |   | 5 |   |   |         |             |          | all    | x      | x      | x          |   |  |  | <ul style="list-style-type: none"> <li>• [Saltelli et al, 2008]</li> <li>• [Morgan &amp; Henrion, 1990]</li> </ul> |
| 727. | Sentinel             | Min       | Dat     | 2005 | Sentinel monitors airline safety data, enabling users to pinpoint potential areas of concern. Incident reports are filed in a data repository for trending and analysis. Sentinel analyses this accumulated information and helps detect patterns and trends which are significant or may become significant. The results can be transmitted in real time to safety specialists within an organisation and can be shared with other Sentinel users around the world. Aim is to support adopting preventative strategies and target resources.   | Developed by Mercator (the IT division of Emirates Airline) by updating WinBASIS and BASIS. It is in use at over 100 airlines and aviation companies.   |                         |   |   |   |   |   |   |   | 7       | 8           | aviation | x      | x      | x      | x          | x |  | <ul style="list-style-type: none"> <li>• www.mercator.com</li> </ul>         |  |
| 728. | sequenceMiner        | Min       | Dat     | 2006 | Approach to model the behaviour of discrete sensors in an aircraft during flights in order to discover atypical behavior of possible operational significance, e.g. anomalies in discrete flight data. The sequenceMiner analyzes large repositories of discrete sequences and identifies operationally significant events. The focus is on the primary sensors that record pilot actions. Each flight is analyzed as a sequence of events, taking into account both the frequency of occurrence of switches and the order in which switches change values. It clusters flight data sequences using the normalized longest common subsequence (nLCS) as the similarity measure and using algorithms based on a Bayesian model of a sequence clustering that detect anomalies inside sequences. In addition, it provides explanations as to why these particular sequences are anomalous. The sequenceMiner algorithm operates by first finding groups of similar flight sequences, and then finding those sequences that are least similar to any of the groups. It uses the normalized longest common subsequence as the similarity measure, and ideas from bioinformatics such as Multiple Sequence Alignment to determine the degree to which a given sequence is anomalous. | sequenceMiner was developed with funding from the NASA Aviation Safety Program. The approach is stated to be general and not restricted to a domain, hence can be applied in other fields where anomaly detection and event mining would be useful.   |                         |   |   |   |   |   |   |   | 7       | 8           | aviation | x      | x      | x      |            |   |  | <ul style="list-style-type: none"> <li>• [Budalakoti et al, 2006]</li> </ul> |  |

| 729. | SESAR SRM (Single European Sky Air traffic management Research Safety Reference Material) | Int    | OpR      | 2013 | This is a framework with guidance material, which supports the development of safety cases for gate-to-gate air navigation services. Aim is to establish safety arguments addressing the system engineering lifecycle up to and including the pre-industrialisation phase of an operational improvement (OI). In each lifecycle stage the aim is to build a 'success case' that shows that any pre-existing hazards are acceptable with the introduction of the new OI, as well as a 'failure case' that shows that any new hazards introduced by the OI are acceptable. Safety performance requirements are developed to be fed back to the further development of the OI, as input to the next lifecycle stage. | Developed by Eurocontrol with partners, and is being regularly updated. Is used in the SESAR (Single European Sky ATM Research) programme for safety analysis and assurance that the SESAR-developed operational improvements are acceptably safe. It is built on EATMP SAM, SAME, and AIM, with references to many other methods in its Guidance Material. | 1                       | 2 | 3 | 4 | 5 | 6 | 7 | 8 | ATM                                      | x           | x | x | x |   |            | • [Fowler et al, 2011]   |
| 730. | SEU (Subjective Expected Utility)   | Math   | Dec      | 1954 | SEU aims to transform concepts like safety, quality of life, and aesthetic value into a form that can be used for cost/benefit analyses. The theory of SEU combines two subjective concepts: first, a personal utility function, and second a personal probability distribution (based on Bayesian probability theory). The likelihood of an event (which is subject to human influence) occurring (the expectancy variable) is seen as the subjective probability that the outcome will occur if a behavior is undertaken. The value variable (the subjectively determined utility of the goal) is multiplied by the expectancy. The product is the subjective expected utility.                                 | Promoted by L.J. Savage in 1954   |                         |   |   |   | 5 |   |   |   | finance, social                          |             | x |   |   |   |            | • [Savage, 1954]<br>• [FAA HFW]                                  |
| 731. | Severity Distribution Analysis  | Step   | Par, OpR | 1982 | Is used in estimations of the probability of severe accidents at a workplace and in comparing different workplaces with respect to the expected severity of the accidents. It is based on the accidents for a specified period of time and follows a step-wise procedure: 1) Arrange the accidents by consequence in an ascending order; 2) Divide the highest registered consequence value into intervals such that each interval has approximately the same size on a logarithmic scale; 3) Tally the number of accidents in each interval and the cumulative number; 4) Calculate the cumulative percentage of accidents for each interval and use a log-normal paper to plot the results.                     | See also Comparison Risk Analysis.  |                         |   |   |   |   |   |   | 8 | finance, road, manufacturing, healthcare | x           |   |   |   | x |            | • [Kjellen, 2000]  |
| 732. | SFG (Signal Flow Graph)   | Stat   | Mod      | 1966 | Identifies the important variables and how they relate within a given technical system. The graph consists of nodes and directed branches; the nodes are the variables of a set of linear algebraic relations. The analysis is conducted by selecting a system output variable and then identifying all the variables that could influence this. The network presents the system variables as nodes connected by flows.   | Also known as Mason graph. Related to State Transition Diagrams. An SFG can only represent multiplications and additions. Multiplications are represented by the weights of the branches; additions are represented by multiple branches going into one node.   |                         | 2 |   |   |   |   |   |   | electronics                              |             |   |   | x |   |            | • [Kirwan & Ainsworth, 1992]<br>• [HEAT overview]<br>• [FAA HFW] |

| 733. | SFMEA or SWFMEA (Software Failure Modes and Effects Analysis) | Tab    | SwD     | 1979          | This technique identifies software related design deficiencies through analysis of process flow-charting. It also identifies areas for verification/validation and test evaluation. It can be used to analyse control, sequencing, timing monitoring, and the ability to take a system from an unsafe to a safe condition. This should include identifying effects of hardware failures and human error on software operation. It uses inductive reasoning to determine the effect on the system of a component (includes software instructions) failing in a particular failure mode. SFMEA was based on FMEA and has a similar structure.   | Software is embedded into vital and critical systems of current as well as future aircraft, facilities, and equipment. SFMEA can be used for any software process; however, application to software controlled hardware systems is the predominate application. Unlike Hardware FMEA, which analyzes both severity and likelihood of the failure, an SFMEA usually analyzes only the severity of the failure mode. |                         |   |   | 3 |   |   |   |   |         |             |        | avionics, space                             | x      | x      |            |  |  | <ul style="list-style-type: none"> <li>[FAA00]</li> <li>[Lutz &amp; Woodhouse, 1996]</li> <li>[ΣΣ93, ΣΣ97]</li> <li>[Pentti &amp; Atte, 2002]</li> <li>[Ippolito &amp; Wallace, 1995]</li> <li>[Reifer, 1979]</li> </ul> |
| 734. | SFTA (Software Fault Tree Analysis)                           | Stat   | SwD     | 1983          | This technique is employed to identify the root cause(s) of a “top” undesired event. To assure adequate protection of safety critical functions by inhibits interlocks, and/or hardware. Based on Fault Tree Analysis. If a branch of a hardware FTA refers to system software, the SFTA is applied to that portion of software controlling that branch of the hardware FTA.  | Any software process at any level of development or change can be analysed deductively. However, the predominate application is software controlled hardware systems. See also FTA.  |                         |   |   |   | 4 | 5 |   |   |         |             |        | avionics, space                             | x      | x      |            |  |  | <ul style="list-style-type: none"> <li>[FAA00]</li> <li>[Leveson, 1995]</li> <li>[NASA-GB-1740.13-96]</li> <li>[ΣΣ93, ΣΣ97]</li> </ul>   |
| 735. | SHA (System Hazard Analysis)                                  | Step   | HZA     | 1993 or older | System Hazard Analysis purpose is to concentrate and assimilate the results of the Sub-System Hazard Analysis (SSHA) into a single analysis to ensure the hazards of their controls or monitors are evaluated to a system level and handled as intended. SHA build on preliminary hazard analysis (PHA) as a foundation. SHA considers the system as a whole and identifies how system operation, interfaces and interactions between subsystems, interface and interactions between the system and operators, and component failures and normal (correct) behaviour could contribute to system hazards. The SHA refines the high-level design constraints generated during PHA. Conformance of the system design to the design constraints is also validated. Through SHA, safety design constraints are traced to individual components based on the functional decomposition and allocation. | Any closed loop hazard identification and tracking system for an entire program, or group of subsystems can be analysed. Identifies system design features and interface considerations between system elements that create hazards. Inductive.  |                         |   |   | 3 | 4 |   |   |   |         |             |        | aviation, defence, healthcare food chemical | x      |        |            |  |  | <ul style="list-style-type: none"> <li>[FAA00]</li> <li>[FAA tools]</li> <li>[SEC-SHA]</li> <li>[ΣΣ93, ΣΣ97]</li> </ul>  |
| 736. | SHARD (Software Hazard Analysis and Resolution in Design)     | Tab    | SwD     | 1994          | Adaptation of HAZOP to the high-level design of computer-based systems. Provides a structured approach to the identification of potentially hazardous behaviour in software systems. SHARD uses a set of guidewords to prompt the consideration of possible failure modes. Based on software failure classification research, five guidewords are used in the SHARD method - omission, commission, early, late and value failure. These guidewords are applied systematically to functions and/or flows in a software design. Use of SHARD facilitates the systematic identification of software contributions to system level hazards and the definition of associated software safety requirements.   | Developed by DCSC (Dependable Computing Systems Centre). Early version was referred to as CHAZOP (Computer HAZOP)  |                         |   |   | 3 |   |   | 6 |   |         |             |        | defence                                     |        | x      |            |  |  | <ul style="list-style-type: none"> <li>[McDermid, 2001]</li> <li>[McDermid &amp; Pumfrey]</li> <li>[Mauri, 2000]</li> </ul>  |

| 737. | SHARP<br>(Systematic Human Action Reliability Procedure)             | Int    | HRA              | 1984                | Helps practitioners picking up the right Human Reliability Analysis method to use for a specific action / situation. It employs a 4-phase procedure: 1) Identification of potential human errors (using detailed description of operator tasks and errors, and techniques like FMEA); 2) Selecting significant errors (e.g. based on likelihood and whether it leads directly to undesirable event); 3) Detailed analysis of significant errors (likelihood analysis); 4) Integration into a system model (studying the dependence between human errors and system errors and the dependence of human errors on other errors). SHARP suggests a number of techniques to be used.                           | Developed by Hannaman & Spurgin (Electric Power Research Institute).  |                         |   |   | 3 | 4 | 5 |   |   |         |             |        | nuclear  |        |        | x          |  |  |   | <ul style="list-style-type: none"> <li>• [MUFTIS3.2-I, 1996]</li> <li>• [Wright et al, 1994]</li> </ul> |
| 738. | SHCM<br>(Software Hazard Criticality Matrix)                         | Tab    | SwD              | 1993<br>or<br>older | The Software Hazard Criticality Matrix (SHCM) assists the software safety engineering team and the subsystem and system designers in allocating the software safety requirements between software modules and resources, and across temporal boundaries (or into separate architectures). Software hazards are allocated to cells in a matrix with vertically the various control categories (i.e. the level at which the software controls the critical hardware systems or components), and horizontally the effects of the hazard (catastrophic, critical, marginal, negligible). The software control measure of the SHCM also assists in the prioritization of software design and programming tasks. | Available in military standard MIL-STD-882C.  |                         |   |   |   |   |   | 6 |   |         |             |        | (defence)  |        | x      |            |  |  | <ul style="list-style-type: none"> <li>• [FAA00]</li> </ul>   |   |
| 739. | SHEL or SHELL model  | Stat   | Mod              | 1972                | In the SHELL model, S=Software (procedures, symbology, etc.); H=Hardware (machine); E=Environment (operational and ambient); L=Liveware (human element). The model has the form of a plus-sign (+), consisting of 5 blocks, each with one letter of SHELL in it, with one of the 'L's in the middle. A connection between blocks indicates an interconnection between the two elements. The match or mismatch of the blocks (interconnection) is just as important as the characteristics described by the blocks themselves.  | Developed by Prof Dr. E. Edwards of Birmingham University in 1972. Modified in about 1975 by Cpt Frank Hawkins of KLM, who added the second L. The m-SHELL model of Kawano includes the element management. SCHELL, where C stands for Cultural, also includes management. See also 5M Model. |                         | 2 |   |   |   |   |   |   |         |             |        | aviation, aircraft, healthcare, ergonomics, nuclear, maritime, rail, manufacturing, road, management | x      | x      | x          |  |  | <ul style="list-style-type: none"> <li>• [Edwards, 1972]</li> <li>• [Edwards, 1988]</li> <li>• [FAA00]</li> <li>• [Hawkins, 1993]</li> <li>• [ICAO Doc 9806]</li> <li>• [Itoh et al, 2004]</li> <li>• [Kawano, 2002]</li> <li>• [Keightley, 2004]</li> <li>• [Perry &amp; Perezgonzalez, 2010]</li> <li>• [Silva &amp; Trabasso, 2013]</li> </ul> |   |
| 740. | SHERPA<br>(Systematic Human Error Reduction and Prediction Approach) | Stat   | HRA<br>,<br>Task | 1986                | Focuses on particular task types depending on the industry concerned. Root of TRACER, HERA I, HERA II. The description of activities developed using HTA is taken task-by-task and scrutinised to determine what can go wrong. Each task is classified into one of 5 basic types (i.e. checking, selection, action, information communication and information retrieval) and a taxonomy of error types is applied. The immediate consequences for system performance are recorded. For each error type, an assessment of likelihood and criticality is made. Finally, potential recovery tasks and remedial strategies are identified.   | Developed by D.E. Embrey. Related to SCHEMA and PHEA. Equivalent to FMEA used in reliability Technology. Also does it work like a human HAZOP. Originally developed for nuclear domain, but now also applied in other domains.  |                         |   | 3 |   | 5 | 6 |   |   |         |             |        | nuclear, aviation, healthcare, electronics   |        |        | x          |  |  | <ul style="list-style-type: none"> <li>• [Kirwan, 1994]</li> <li>• [Kirwan, Part 1, 1998]</li> <li>• [FAA HFW]</li> </ul>   |   |

| 743. | SLIM (Success Likelihood Index Method)         | Step   | HRA, Par | 1981      | Estimates human error probabilities. Two modules: MAUD (Multi-Attribute Utility Decomposition, used to analyse a set of tasks for which human error probabilities are required) and SARA (Systematic Approach to the Reliability Assessment of Humans, used to transform success likelihoods into human error probabilities (HEP)).  | Developed by D.E. Embrey et al, Brookhaven National Laboratory, Department of Nuclear Energy. Similar to APJ. Can be reserved for difficult HEP assessments that HEART and THERP are not designed for.   |                         |   |   |   |   | 5 |   |   |         |             | nuclear, chemical, manufacturing, security |        |        |        | x          |   | <ul style="list-style-type: none"> <li>[Humphreys, 1988]</li> <li>[Kirwan &amp; Kennedy &amp; Hamblen]</li> <li>[Kirwan, 1994]</li> <li>[MUFTIS3.2-I, 1996]</li> <li>[GAIN ATM, 2003]</li> </ul> |
| 744. | SLM (Step Ladder Model)                        | Stat   | HFA      | 1976      | SLM is an information-processing model that assumes an expected sequence of mental operations in the course of decision making. The 8 steps are 'Activation', Observe, Identify, Interpret and Evaluate, Define Task, Formulate Procedure, and Execute. Errors can occur when operators avoid intermediate steps to decrease mental demand. Three types of decisions are conceptualised (skill, rule, knowledge-based model): "Skill-based" decisions proceed directly from detection to the execution with few intermediate mental steps. "Rule-based" decisions require a mental representation of the system state (e.g. the air traffic situation), and the selection of an appropriate procedure based on that recognition. "Knowledge-based" decisions proceed through causal reasoning. | Developed by Rasmussen. Considers cognitive elements not only behavioural patterns.  |                         | 2 | 3 | 4 |   |   |   |   |         |             | security, (nuclear), (aviation)            |        |        |        | x          |   | <ul style="list-style-type: none"> <li>[FAA HFW]</li> <li>[Rasmussen, 1986]</li> <li>[Weitzman, 2000]</li> <li>[GAIN ATM, 2003]</li> <li>[Carayon &amp; Kraemer, 2002]</li> </ul>                |

| 745. | SMHA<br>(State Machine Hazard Analysis)  | Stat   | Hzi, Mod | 1987 | Used to identify software-related hazards. A state machine is a model of the states of a system and the transitions between them. Software and other component behaviour is modelled at a high level of abstraction, and faults and failures are modelled at the interfaces between software and hardware.  | Often used in computer science. For complex systems, there is a large number of states involved. Related to Petri nets. Procedure can be performed early in the system and software development process.   |                         |   |   | 3 | 4 |   |   |   |         |             |           | avionics                    | x      |        |            |   |   | <ul style="list-style-type: none"> <li>• [Leveson, 1995]</li> <li>• [Houmb, 2002]</li> </ul> |
| 746. | SMORT<br>(Safety Management Organisation Review Technique)   | Tab    | Org, Ret | 1987 | SMORT is a simplified modification of MORT. This technique is structured by means of analysis levels with associated checklists, while MORT is based on a comprehensive tree structure. The SMORT analysis includes data collection based on the checklists and their associated questions, in addition to evaluation of results. The information can be collected from interviews, studies of documents and investigations. It can be used to perform detailed investigation of accidents and near misses. It also serves as a method for safety audits and planning of safety measures. | Developed by U. Kjellén et al. (Norway).   |                         |   |   |   |   |   |   |   |         |             |           | no-domain-found             |        |        |            |   | x   | <ul style="list-style-type: none"> <li>• [Kjellen, 2000]</li> <li>• [NEMBS, 2002]</li> </ul> |
| 747. | SOAM<br>(Systematic Occurrence Analysis Methodology)   | Step   | Org, Ret | 2005 | Aim is to broaden the focus of an investigation from human involvement issues, also known as “active failures of operational personnel” under Reason’s original model, to include analysis of the latent conditions deeper within the organisation that set the context for the event. The SOAM process follows six steps: 1) Review gathered data; 2) Identify barriers; 3) Identify human involvement; 4) Identify contextual conditions; 5) Identify organisational factors; 6) Prepare SOAM chart.  | Reason’s original Swiss Cheese model has been adapted in accordance with a “just culture” philosophy. ‘Unsafe acts’ are referred to as Human Involvement; ‘Psychological precursors of unsafe acts’ as Contextual conditions; ‘Fallible decisions’ as Organisational and system factors. Data gathering is according to the SHELL model. |                         |   |   |   |   |   |   |   |         |             | ATM       | x                           |        | x      | x          | x | <ul style="list-style-type: none"> <li>• [Licu, 2007]</li> <li>• [Eurocontrol, 2005]</li> <li>• [Arnold, 2009]</li> </ul>       |  |
| 748. | SOAR<br>(State, Operator, and result)  | Int    | HFA      | 1983 | Soar uses a set of principles and constraints to construct models of knowledge-based behaviour, including interaction with external systems and environments.   | Developed by J. Laird and A. | 750. | SOFIA<br>(Sequentially<br>Outlining and<br>Follow-up Integrated<br>Analysis) | Stat   | HZA     | 2001                | SOFIA is an analytical and graphical method supporting the process of ATM safety occurrence investigation to distinguish between the causes of an occurrence. It is for use during factual information gathering; event reconstruction; event analysis and issuing recommendations. It refers to the three layers in the Swiss Cheese model: unsafe acts, local workplace factors and organisational factors. The method uses event/ condition building blocks to describe the causal chain leading to an occurrence. Building blocks are associated with a unique actor at a particular moment in time. Actor(s) can be any representative player in the occurrence, including persons but also technical systems or any attribute that is important and is dynamic in the course of particular occurrence like separation. | Developed in EUROCONTROL in collaboration with the Bulgarian Air Traffic Services Authority. Link with TOKAI and HERA.  |                         |   |   |   |   |   |   |   |         |             | 8      | ATM      | x      |        | x          | x |  |  | • [Blajev, 2003] |
| 751. | Software Testing   | Gen    | SwD     | 1976<br>or<br>older | Software Testing provides an objective, independent view of the software to allow the business to appreciate and understand the risks at implementation of the software. Test techniques include, but are not limited to, the process of executing a program or application with the intent of finding software bugs. Several methods of testing exist, e.g.:<br>• Assertions and plausibility checks.<br>• Avalanche/Stress Testing.<br>• Back-to-back Testing.<br>• Boundary value analysis.<br>• Equivalence Partitioning and Input Partition Testing.<br>• Probabilistic testing. Self testing and Capability testing.<br>• Tests based on Random Data.<br>• Tests based on Realistic data.<br>• Tests based on Software structure.<br>• Tests based on the Specification.   | See also<br>• Code Analysis<br>• Code Coverage<br>• Code Inspection Checklists<br>• Code Logic Analysis.<br>• Complexity Models<br>• Control Flow Checks<br>• Interface Testing.<br>• Test Adequacy Measures. |                         |   |   |   |   |   |   |   |         |             | 7      | software |        | x      |            |   |  | • [Bishop, 1990]<br>• [EN 50128, 1996]<br>• [ISO/IEC 15443, 2002]<br>• [Jones et al, 2001]<br>• [Rakowsky] |                  |
| 752. | Software Time-out<br>Checks  | Gen    | Des     | 1980<br>or<br>older | Aim is to provide time limits for software running non-deterministic tasks.  | Useful to provide determinism on non-deterministic task in safety computer systems. Related to error-recovery and time-out checks.  |                         |   |   |   |   |   |   |   |         |             | 6      | software |        | x      |            |   |  | • [Bishop, 1990]   |                  |

| 753. | SOL<br>(Sicherheit durch Organisationales Lernen, Safety through Operational Learning) | Stat   | Ret     | 1997 | SOL aims at facilitating organisational learning from events by supporting the process of analysing events, ensuring its standardised conduct and mobilising expert knowledge and creativity in the analysis. The SOL method covers the identification of human factors as well as technical, organisational and management factors. Phases are: 1) Collect the event objective data, without questioning its significance. 2) Organise the data into elements of the event as individual actions performed by the personnel, organisational unit or systems. 3) Classify the actions chronologically and represent in an actor-action-time illustration. The method uses a predetermined set of direct causes and contributing factors, and proposes questions to be addressed to help identify the contributing causes.   | Developed by Bernhard Wilpert, Berlin University of Technology in collaboration with the TÜV. Originally developed for the nuclear industry, but a version for chemical industry was developed as well. SOL has been adopted by the Swiss and German nuclear industries as standard procedure for their in-depth event analyses.                                 |                         |   |   |   |   |   |   |   |         | 8           | nuclear, chemical, police |        |        | x      |            |   | x   | <ul style="list-style-type: none"> <li>• [Ziedelis &amp; Noel, 2011]</li> <li>• [Izso et al, 2019]</li> </ul> |
| 754. | SOM<br>(SDL-Oriented Method or Structured Object Model)                                | Int    | Des     | 1979 | SOM is a development language and methodology covering the development of systems consisting of software and hardware from requirements to implementation, with special emphasis on real-time systems.  | SOM was initially spelled Structure-Oriented Method, but this was later adjusted to SDL-Oriented Method, to emphasize its suitability for SDL (Specification and Description Language).Based on Extended Finite State Machines, related to SBC, CCS, SDL, SADT. Tools available.   |                         |   | 2 |   |   |   |   |   | 6       |             | electronics, management   | x      | x      |        |            |   | <ul style="list-style-type: none"> <li>• [Bishop, 1990]</li> <li>• [Kraemer, 2008]</li> </ul> |   |
| 755. | SORA<br>(Specific Operations Risk Assessment)  | Step   | OpR     | 2019 | The SORA is a methodology for the classification of the risk posed by a drone flight mission lying into the specific category of operations. It is based on the evaluation of ground risk and air risk. The ground risk is related to the risk of a person, property or critical infrastructure being struck by an unmanned aircraft (UA) and therefore considers the operating environment with respect to the population density, the type of operation (in or beyond Visual Line of Sight) and the UA size. The determination of the air risk considers the probability of encountering manned aircraft in the airspace, which is chiefly derived from the density and composition of manned air traffic in the airspace. After obtaining the Ground Risk Class and Air Risk Class respective values, the combination of both leads to the final rating of the mission, the so-called SAIL (Specific Assurance and Integrity Level), with a high value representing a high potential risk. Mitigations, which can be either additional equipment or changes to the operation including subscription to a U-space service, can be used to reduce the ground and air risks and thereby the SAIL. | The SORA concept was developed by Working Group 6 (WG6) of the Joint Authorities for the Rulemaking of Unmanned Systems (JARUS). It has been endorsed by the European Aviation Safety Agency (EASA) as an Acceptable Means of Compliance (AMC) to fulfil the requirements of the EU Regulations (Basic Regulation, Implementing Act, Delegated Act and Annexes). |                         |   |   | 3 |   |   | 5 | 6 |         |             | aviation                  | x      |        |        |            | x | <ul style="list-style-type: none"> <li>• [SORA, 2019]</li> </ul>                              |   |

| 760. | SPEAR<br>(System for Predictive Error Analysis and Reduction) | Tab    | HRA<br>,<br>Task | 1993                | SPEAR uses an error taxonomy consisting of action, checking, retrieval, transmission, selection and planning errors and operates on a HTA of the task under analysis. The analyst considers a series of performance-shaping factors for each bottom level task step and determines whether or not any credible errors could occur. For each credible error, a description of it, its consequences and any error reduction measures are provided.  | Taxonomic approach to Human Error Identification (HEI) similar to SHERPA. SPEAR was developed by the Centre for Chemical Process Safety (CCPS) for use in the American processing industry's HRA programme.  |                         |   |   |   |   | 5 |   |   |         |             |        | chemical   |        |        | x          |  |  |  |  | <ul style="list-style-type: none"> <li>• [Baber et al, 2005]</li> <li>• [Stanton et al, 2005]</li> </ul> |
| 761. | Specification Analysis  | Gen    | SwD              | 1990<br>or<br>older | Specification Analysis evaluates the completeness, correctness, consistency and testability of software requirements. Well-defined requirements are strong standards by which to evaluate a software component. Specification analysis evaluates requirements individually and as an integrated set.  |  |                         |   |   |   |   |   |   |   | 7       |             |        | software,<br>(avionics),<br>(space)                            |        |        | x          |  |  |  |  | <ul style="list-style-type: none"> <li>• [NASA-GB-1740.13-96]</li> </ul>                                 |
| 762. | SpecTRM<br>(Specification Tools and Requirements Methodology) | Int    | Des              | 2002                | SpecTRM helps system and software engineers develop specifications for large, complex safety-critical systems. It enables engineers to find errors early in development so that they can be fixed with the lowest cost and impact on the system design. It also traces both the requirements and design rationale (including safety constraints) throughout the system design and documentation, allowing engineers to build required system properties into the design from the beginning. SpecTRM provides support for manual inspection, formal analysis, simulation, and testing, while facilitating communication and the coordinated design of components and interfaces. | Developed by Nancy Leveson. Is based on the principle that critical properties must be designed into a system from the start. As a result, it integrates safety analysis, functional decomposition and allocation, and human factors from the beginning of the system development process. |                         |   | 2 | 3 |   |   |   | 6 |         |             |        | (aircraft),<br>(ATM),<br>(aviation),<br>(avionics),<br>(space) |        |        | x          |  |  |  | <ul style="list-style-type: none"> <li>• [Leveson, 2002]</li> <li>• [SafeWare web]</li> <li>• [Leveson et al, 1998]</li> </ul>                   |  |
| 763. | SPFA<br>(Single-Point Failure Analysis)                       | Step   | HzA              | 1980                | This technique is to identify those failures that would produce a catastrophic event in items of injury or monetary loss if they were to occur by themselves. The SPFA is performed by examining the system, element by element, and identifying those discrete elements or interfaces whose malfunction or failure, taken individually, would induce system failure. Next, the local and system effects of these failure modes are determined.   | This approach is applicable to hardware systems, software systems, and formalised human operator systems. It is sometimes referred to as another standard name for FMEA.   |                         |   |   | 3 |   |   |   |   |         |             |        | nuclear, space   | x      | x      | x          |  |  |  | <ul style="list-style-type: none"> <li>• [FAA AC431]</li> <li>• [FAA00]</li> <li>• [ΣΣ93, ΣΣ97]</li> </ul>                                       |  |

| 764. | SRCA<br>(Safety Requirements Criteria Analysis)               | Step   | Val              | 1993                | The objective of the SRCA is to ensure that the intent of the system safety requirements (SSRs) in the system is met and that the SSRs eliminate, mitigate, and/or control the identified causal factors. The SRCA also provides the means for the safety engineer to trace each SSR from the system level specification, to the design specifications, to individual test procedures and test results' analysis. The safety engineer should also identify all safety-critical SSRs to distinguish them from safety-significant SSRs. The SRCA is a "living" document that the analyst constantly updates throughout the system development.                                    | Safety-critical SSRs are those that directly influence a safety-critical function, while safety-significant SSRs are those that indirectly influence safety-critical functions.  |                         |   |   |   |   |   |   |   | 7       |             |        | navy, (aircraft)   | x      | x      |            |  |  |  | <ul style="list-style-type: none"> <li>• [FAA00]</li> <li>• [Software SSH, 1999]</li> <li>• [Ericson, 2005]</li> <li>• [MIL-STD 882C]</li> </ul> |  |

| 765. | SRG CAP 760<br>(Safety Regulation Group CAA Publication 760) | Int    | OpR     | 2006 | CAP 760 provides guidance on the conduct of hazard identification, risk assessment and the production of safety cases for aerodrome operators and air traffic service providers. The risk assessment and mitigation guidance addresses seven process steps: 1) System description; 2) Hazard and consequence identification; 3) Estimation of the severity of the consequences of the hazard occurring; 4) Estimation/assessment of the likelihood of the hazard consequences occurring; 5) Evaluation of the risk; 6) Risk mitigation and safety requirements; 7) Claims, arguments and evidence that the safety requirements have been met and documenting this in a safety case. There are feedback loops from steps 5, 6 and 7 back to earlier steps, based on acceptability of risks analysed. | Developed by UK CAA's Safety Regulation Group (SRG). The method refers to other techniques to support some of the steps, e.g. FMECA, HAZOP, ETA. |                         | 2 | 3 | 4 | 5 | 6 | 7 |   |         | (ATM),<br>(airport)                | x      |        | x      | x      |            |  | • [CAP 760, 2006]   |
| 766. | SRHA<br>(Software Requirements Hazard Analysis)              | Tab    | SwD     | 1994 | In an SRHA, software requirements are divided into sets, each of which addresses a particular quality (e.g. accuracy, capacity, functionality, reliability, robustness, safety, security) of the software. SRHA examines each quality, and each requirement within the quality, against a set of guide phrases to assess the likely impact on hazards. Output of SRHA is a list of software hazards, a criticality level for each hazard that can be affected by the software, acriticality level for each software requirement, an analysis of the impact on hazards of the software when it operates correctly or incorrectly with respect to meeting each requirement.   |  |                         |   | 3 |   | 5 |   |   |   |         | software,<br>(space),<br>(defence) |        | x      |        |        |            |  | • [Lawrence, 1995]  |
| 767. | SRK<br>(Skill, Rule and Knowledge-based behaviour model)     | Stat   | HRA     | 1981 | Psychologically-based model, assuming three levels: 1) Skill-based level: A query of an agent is accepted and by searching the knowledge-base, proper immediate action is selected. 2) Rule-based level: A query of an agent is accepted and a case data base is consulted to determine the action. 3) Knowledge-based level: A query is accepted and the agent uses its knowledge base to interact with the other agent and identify the actual needs. After this problem identification level, the proper action is determined by consulting other agents.  | Developed by Jens Rasmussen of Risø laboratories. Rarely used as model on its own. Also referred to as Human Error Model.                        |                         | 2 |   |   |   |   |   |   |         | chemical,<br>aviation,<br>nuclear  |        |        | x      |        |            |  | • [Reason, 1990]<br>• [Cacciabue, 1998]<br>• [SAP15]<br>• [Kirwan, Part 1, 1998]<br>• [SRK] |

| 781. | STEADES (Safety Trend Evaluation, Analysis & Data Exchange System)                          | Min    | Dat      | 2001 | STEADES is a database containing de-identified incident reports with over 350,000 records. It provides a forum for the analysis, trending, and general inquiry of the leading indicators of industry safety in order to develop a comprehensive list of prevention strategies. It can be used for global safety trending, customised analysis projects, ad-hoc mini-analysis requests. Results can be provided to members: -) Daily, through the safety data management & analysis (SDMA) website and ad-hoc mini-analysis requests; -) Monthly: with the STEADES safety bulletin, providing a regular pulse of accident information by email; -) Quarterly: with the STEADES safety trend analysis report, highlighting the latest safety features found in the incident data; -) Yearly: with the IATA safety report, featuring in-depth synopsis of the previous years accidents, including analysis of contributing factors. | STEADES was an initiative of the IATA Safety Committee. The data is gathered from airlines.   |                         |   |   |   |   |   |   |   |         |             | 8      | aviation, ATM, airport | x   |        |            | x | x |   |   | • [STEADES]  |
| 782. | STEP or STEPP (Sequentially-Timed Events Plot or Sequential Timed Event Plotting Procedure) | Stat   | OpR, Ret | 1987 | This method is used to define systems; analyse system operations to discover, assess, and find problems; find and assess options to eliminate or control problems; monitor future performance; and investigate accidents. It is an events-analysis-based approach in which events are plotted sequentially (and in parallel, if appropriate) to show the cascading effect as each event impacts on others. It is built on the management system embodied in the Management Oversight and Risk Tree (MORT) and system safety technology.  | Developed by Hendrick and Benner in 1987. In accident investigation, a sequential time of events may give critical insight into documenting and determining causes of an accident. STEP is a refinement of Multilinear Event Sequencing (MES). It is used for complex events with many actors, and when the time sequence is important. |                         |   |   |   |   |   |   |   |         | 6           |        | 8                      | aviation, (nuclear), (chemical), (mining) | x      |            |   |   | x   | x | • [FAA00]<br>• [ΣΣ93, ΣΣ97]<br>• [Wilson & Stanton, 2004]<br>• [Henrick & Brenner, 1987] |
| 783. | Stochastic Differential Equations on Hybrid State Space                                     | Math   | Mod      | 1990 | These are differential equations on hybrid state space with stochastic elements. The stochastic elements may model noise variations in processes, or the occurrence of random events. The advantage of using this esoteric modelling formalism is the availability of powerful stochastic analysis tools.  | Relation with some Petri nets also established. These Petri nets can be used to make a compositional specification of the operation considered which fit the esoteric but powerful stochastic differential equation models.   |                         |   |   |   | 4 |   |   |   |         |             |        | ATM                    | x   | x      | x          | x | x | • [Blom, 1990]<br>• [Blom, 2003]<br>• [Krystul & Blom, 2004]<br>• [Krystul & Blom, 2005]<br>• [Everdij & Blom, 2004a]<br>• [Krystul et al, 2012]<br>• [Krystul et al, 2007] |   |  |

| 784. | STPA<br>(Systems Theoretic Process Analysis)                                    | Tab    | Mit     | 2008 | STPA is a qualitative hazard analysis technique that assumes that accidents occur not simply because of component failures, but because constraints on component behavior are inadequately enforced. It is used to identify instances of inadequate control that could lead to the presence of hazards, to identify safety-related constraints necessary to ensure acceptable risk, and to gain insight into about how those constraints may be violated. This information can be used to control, eliminate, and mitigate hazards in the system design and operation. STPA can be applied to existing designs, or in a proactive way to help guide the design and system development. | STPA is based on STAMP and was developed by Nancy Leveson and co-authors.  |                         |   |   | 3 | 4 |   | 6 |   |         |             | avionics, ATM, aviation, oil&gas, defence, space, rail, food | x      | x      | x      | x          | x | <ul style="list-style-type: none"> <li>[Leveson, 2011]</li> <li>[Thomas &amp; Leveson, 2011]</li> </ul>        |
| 785. | STRES Battery<br>(Standardized Tests for Research with Environmental Stressors) | Tab    | HFA     | 1989 | The STRES Battery is a computer-supported test battery for the examination of mental performance. It is comprised of seven tests: Reaction Time, Mathematical Processing, Memory Search, Spatial Processing, Unstable Tracking, Grammatical Reasoning, and Dual Task (unstable tracking with concurrent memory search). To evaluate stressors the performance of participants is compared under controlled conditions to determine the effects of stressors such as sleep deprivation, fatigue, monotony and boredom, illnesses' toxic fumes, hypoxia, temperature extremes, and alcohol and other drugs.  | Recommended by the committee for psychological issues in AGARD (Advisory Group for Aerospace Research and Development). Most of the tasks are based on the CTS (Criterion Task Set) battery. |                         |   |   |   |   | 5 |   |   |         |             | healthcare, ergonomics, space                                |        |        | x      |            |   | <ul style="list-style-type: none"> <li>[FAA HFW]</li> <li>[DLR AGARD web]</li> <li>[AGARD, 1989]</li> </ul>    |
| 786. | Stress Reduction  | Gen    | Des     |      | Aim is to ensure that under all normal operational circumstances both hardware components and software activity are operated well below their maximum stress levels.   |  |                         |   |   |   |   |   | 6 |   |         |             | no-domain-found  | x      | x      |        |            |   | <ul style="list-style-type: none"> <li>[Bishop, 1990]</li> </ul>   |

| 787. | Strongly Typed Programming Languages  | Gen    | Des     | 1974 | The term strong typing is used to describe those situations where programming languages specify one or more restrictions on how operations involving values having different data types can be intermixed. Strong typing implies that the programming language places severe restrictions on the intermixing that is permitted to occur, preventing the compiling or running of source code which uses data in what is considered to be an invalid way. Aim is to reduce the probability of faults by using a language that permits a high level of checking by the compiler.  | Tools available. | 788. | Structural Safety Analysis                      | Math   | HzA     | 1979 or older | Is used to validate mechanical structures. Inadequate structural assessment results in increased risk due to the potential for latent design problems causing structural failures, i.e., contributory hazards. Structural design is examined via mathematical analysis to satisfy two conditions: 1) Equilibrium of forces, and 2) Compatibility of displacements. The structure considered as a whole must be in equilibrium under the action of the applied loads and reactions; and, for any loading, the displacements of all the members of the structure due to their respective stress-strain relationships must be consistent with respect to each other. | The approach is appropriate to structural design; i.e., airframes, buildings. |                         |   | 3 |   |   |   |   | 6 |         |             | aircraft, nuclear | x      |        |        |            |  | <ul style="list-style-type: none"> <li>• [FAA AC431]</li> <li>• [FAA00]</li> <li>• [ΣΣ93, ΣΣ97]</li> </ul>           |
| 789. | Structure Based Testing or White-Box Testing    | Step   | SwD     | 1995 or older | Software Testing technique. Based on an analysis of the program, a set of input data is chosen such that a large fraction of selected program elements are exercised. The program elements exercised can vary depending upon level of rigour required.  | See also Software Testing.  |                         |   |   |   |   |   |   |   | 7       |             | software          |        | x      |        |            |  | <ul style="list-style-type: none"> <li>• [EN 50128, 1996]</li> <li>• [Rakowsky]</li> </ul>                           |
| 790. | Structure Diagrams                              | Stat   | Des     | 1995 or older | Notation which complements Data Flow Diagrams. They describe the programming system and a hierarchy of parts and display this graphically, as a tree, with the following symbols: 1) rectangle annotated with the name of the unit; 2) an arrow connecting these rectangles; 3) A circled arrow, annotated with the name of data passed to and from elements in the structure chart. Structure Diagrams document how elements of a data flow diagram can be implemented as a hierarchy of program units.  | See also UML.   |                         | 2 |   |   |   |   |   |   |         |             | software          |        | x      |        |            |  | <ul style="list-style-type: none"> <li>• [EN 50128, 1996]</li> <li>• [Rakowsky]</li> </ul>                           |
| 791. | Structured Programming                          | Gen    | Des     | 1967          | Aim is to design and implement the program in a way that makes the analysis of the program practical. This analysis should be capable of discovering all significant program behaviour. The program should contain the minimum of structural complexity. Complicated branching should be avoided. Loop constraints and branching should be simply related to input parameters. The program should be divided into appropriately small modules, and the interaction of these modules should be explicit.   | Tools available. | 793. | SUMI<br>(Software Usability Measurement Inventory)   | Tab    | SwD     | 1993 | This generic usability tool comprises a validated 50-item paper-based questionnaire in which respondents score each item on a three-point scale (i.e., agree, undecided, disagree). SUMI measures software quality from the end user's point of view. The questionnaire is designed to measure scales of:<br>1) Affect - the respondent's emotional feelings towards the software (e.g., warm, happy). 2) Efficiency - the sense of the degree to which the software enables the task to be completed in a timely, effective and economical fashion. 3) Learnability - the feeling that it is relatively straightforward to become familiar with the software. 4) Helpfulness - the perception that the software communicates in a helpful way to assist in the resolution of difficulties. 5) Control - the feeling that the software responds to user inputs in a consistent way and that its workings can easily be internalized. | SUMI was developed by the Human Factors Research Group (HFRG), University College, Cork. |                         |   |   |   |   | 5 |   |   |         |             |                                     | management, software | x      |        |            |  |   | <ul style="list-style-type: none"> <li>• [Kirakowski, 1996]</li> <li>• [SUMI background]</li> <li>• [FAA HFW]</li> <li>• [Van Veenendaal, 1998]</li> </ul> |

| 794. | SUSI<br>(Safety Analysis of User System Interaction) | Stat   | Hzi     | 1993 | HAZOP has been modified to handle Human-computer interaction. The approach adopted in the SUSI methodology is a natural extension of standard hazard analysis procedures. The principal development has been in the creation of an appropriate representation of user system interaction. A major advantage of this process is that the dataflow representation gives an overview of the complete system. The representation of the system as processes and data/control flows is understood by individuals with no software design training, such as operators and users. The review process can lead to detailed insights into potential flaws in the procedures and processes. Designers with different viewpoints are able to use a common representation and believe that it increases their understanding of the total system.   |  |                         | 2 | 3 |   |   | 6 |   |   |         |             | oil&gas, road, healthcare, maritime | x                    |        | x      | x          |  | <ul style="list-style-type: none"> <li>• [Chudleigh &amp; Clare, 1994]</li> <li>• [Falla, 1997]</li> <li>• [Stobart &amp; Clare, 1994]</li> </ul> |  |

| 795. | SWAT<br>(Subjective Workload Assessment Technique) | Tab    | HFA     | 1981          | SWAT is a technique to assess the workload placed on operators of complex human-machine systems. It is designed to be easy to use, low cost, non-intrusive, and sensitive to workload variations. SWAT is composed of subjective operator ratings for three orthogonal dimensions of workload: time load, mental effort load, and psychological stress load. For time load, the question is about how much spare time the operator has. For mental effort load, the question is how much mental effort or concentration is required. For psychological stress load, the question is about confusion, risk, frustration, and anxiety. Each dimension is represented on a three-point scale with verbal descriptors for each point. Individual assessments are scaled and conjoint analysis is carried out on the results to convert them to a single metric of workload. There are 27 possible combinations; the user can decide how to rank order these values. | SWAT is reported to have two main problems: it is not very sensitive for low mental workloads and it requires a time-consuming card sorting pretask procedure. SWAT can also be applied to predict operator workload prior to a system being built; in such applications it is referred to as Pro-SWAT (Projective SWAT). See also Card Sorting. See also Rating Scales (particularly NASA TLX). |                         |   |   |   |   |   |   |   |         |  |        |        |        |        |            |  | <ul style="list-style-type: none"> <li>• [GAIN ATM, 2003]</li> <li>• [HEAT overview]</li> <li>• [FAA HFW]</li> <li>• [Reid et al., 1989]</li> <li>• [Luximon &amp; Goonetilleke, 2001]</li> <li>• [Beevis, 1992]</li> </ul> |
| 796. | SWHA<br>(Software Hazard Analysis)                 | Tab    | HZA     | 1984 or older | The purpose of this technique is to identify, evaluate, and eliminate or mitigate software hazards by means of a structured analytical approach that is integrated into the software development process. The SWHA identifies hazardous conditions incident to safety critical operator information and command and control functions identified by the PHA, SHA, SSHA and other efforts. It is performed on safety critical software-controlled functions to identify software errors/paths that could cause unwanted hazardous conditions. The SWHA can be divided into two stages, preliminary and follow-on.  | This practice is universally appropriate to software systems.  |                         |   | 3 |   | 5 | 6 |   |   |         | healthcare, manufacturing, electronics |        | x      |        |        |            |  | <ul style="list-style-type: none"> <li>• [FAA AC431]</li> <li>• [FAA00]</li> <li>• [ΣΣ93, ΣΣ97]</li> </ul>  |

| 797. | SWIFT<br>(Structured What-IF<br>Technique) | Tab          | Hzi         | 1992 | SWIFT is a systematic team-oriented technique for hazard identification in chemical process plants. It addresses systems and procedures at a high level. SWIFT considers deviations from normal operations identified by brainstorming, with questions beginning “What if...?” or “How could...?”. The brainstorming is supported by checklists to help avoid overlooking hazards. SWIFT relies on expert input from the team to identify and evaluate hazards. There is no single standard approach to SWIFT; it can be modified to suit each individual application. An example protocol is: 1. Identify design boundaries. 2. Define the design intent and normal operating conditions. 3. Choose a question category. 4. Identify a deviation from design intent by applying a system of guidewords/ questions. 5. Identify possible causes for, and consequences of, the deviation. A deviation can be considered "meaningful" if it has a credible cause and can result in harmful consequences. 6. For a meaningful deviation, identify safeguards and decide what action, if any, is necessary. 7. Record the discussion and action. Steps 4 to 7 are repeated until all the guidewords/questions have been exhausted and the team is satisfied that all meaningful deviations have been considered. The team then goes back to Step 3 and repeats the process for the next question category. When all question categories have been exhausted, the team then goes back to Step 1 and repeats the process for the next phase/case. | SWIFT may be used simply to identify hazards for subsequent quantitative evaluation, or alternatively to provide a qualitative evaluation of the hazards and to recommend further safeguards where appropriate. As its name suggests SWIFT will generate answers more quickly than HAZOP but is less thorough in looking at the detail. Developed by DNV.  |                         |   | 3 |   |   | 6 |   |   |  |             | chemical,<br>healthcare | x      |        |        | x          |   |  | • [DNV-HSE, 2001] |
| 798. | Swiss Cheese Model                         | Stat,<br>Gen | Mod,<br>Mit | 1990 | James Reason’s Swiss Cheese model presents human error as a consequence rather than a cause, and should be the starting point for further investigation rather than the end of the search for incident or accident causes. Reason’s key points can be best described as follows: 1) Hazards, errors and other threats to aircraft operations happen all the time, but accidents do not—because most safety threats are caught and corrected by a variety of defenses.2) The aviation environment has multiple or redundant layers of protection—designed to prevent; mistakes or system failures from cascading into accidents; 3) Each layer of protection has flaws. As flaws develop in a layer, the risk for an accident begins to increase; 4) Accidents occur only when sufficient layers of protection are penetrated.   | James Reason’s model of accident causation is intended as an approach toward understanding incidents and accidents and their underlying or contributing factors. Its value, therefore, lies primarily in the orientation or attitude towards investigations it has inspired. The model is usually depicted as a series of slices of cheese with holes. Arrows going through a hole in one slice may be stopped by the next slice having no hole at that point. |                         |   | 3 | 4 |   | 6 |   | 8 | nuclear,<br>aviation, ATM,<br>healthcare,<br>police,<br>chemical,<br>oil&gas |             |                         | x      |        | x      |            | • [GAIN AFSA, 2003]<br>• [Reason, 1990]<br>• [Swiss Cheese] |  |                   |

| 806. | TapRoot   | Int    | Ret              | 1990 | The TapRoot is a suite of tools for accident/incident investigation. It systematically leads an investigator through the techniques/steps used to perform an in-depth accident investigation or incident analysis. TapRoot focuses on uncovering the root causes of accident/incident and helps in proactively improving performance.   | Developed at System Improvements Inc.  |                         |   |   |   |   |   |   |   | 8       |             | manufacturing,<br>oil&gas,<br>aviation,<br>chemical,<br>healthcare,<br>electronics | x                     |        | x      | x          |   | <ul style="list-style-type: none"> <li>• [FAA HFW]</li> <li>• [GAIN ATM, 2003]</li> <li>• [GAIN AFSA, 2003]</li> <li>• [Hutchins, 1995]</li> </ul> |  |   |
| 807. | TARAM<br>(Transport Airplane Risk Assessment Methodology) | Math   | OpR              | 2011 | TARAM aims to give guidance on how to calculate specific levels of risk associated with identifiable design flaws in transport airplanes. The method uses a worksheet in which the user is to fill out estimates of particular parameters. Next, the worksheet computes (through simple mathematical formulas) the following five values: 1) Total uncorrected fleet risk, i.e. number of weighted events statistically expected in the remaining life of the affected fleet if no corrective action is taken. 2). Uncorrected individual risk, i.e. highest probability per flight hour that an exposed individual will be fatally injured. 3). 90-day fleet risk, i.e. total risk within the affected fleet over the next 90 days if no corrective action is taken. 4). Control program fleet risk, i.e. risk within the affected fleet during the period when corrective action is being accomplished. 5). Control program individual risk, i.e. highest probability per flight hour that an exposed individual will be fatally injured. The results are next compared with guidance values as input to decision making. | TARAM aims to support an existing Monitor Safety/Analyze Data (MSAD) regulation, which requires a shift to a mathematical treatment of risk, in furtherance of an effort to implement a safety management system (SMS)-based approach to the aircraft certification process. |                         |   |   |   | 4 | 5 | 6 |   |         |             | aircraft   | x                     | x      |        |            |   | <ul style="list-style-type: none"> <li>• [TARAM Handbook, 2010]</li> </ul>   |  |   |

| 808. | Task Decomposition                          | Gen    | Task    | 1953          | Task decomposition is a structured way of expanding the information from a task description into a series of more detailed statements about particular issues which are of interest to the analyst.  |  |                         | 2 |   |   |   |   |   |               |           | aviation, ATM, defence, navy, space, nuclear, chemical, oil&gas, manufacturing, healthcare, management |        |        | x      |   |  | <ul style="list-style-type: none"> <li>• [Kirwan &amp; Ainsworth, 1992]</li> <li>• [FAA HFW]</li> </ul> |
| 809. | Task Description Analysis                   | Int    | Task    | 1986 or older | Method supported by several different methods designed to record and analyse how the human is involved in a system. It is a systematic process in which tasks are described in terms of the perceptual, cognitive, and manual behaviour required of an operator, maintainer or support person.   |  |                         | 2 |   |   |   |   |   |               | (defence) |  |        | x      |        |   | <ul style="list-style-type: none"> <li>• [MIL-HDBK, 1999]</li> </ul> |   |
| 810. | TCI model (Task-Capability-Interface model) | Gen    | Mod     | 2000          | In this model task difficulty arises out of the interface between the demands of the driving task and the capability of the driver. Task demands depend on factors such as road context, vehicle, speed, and other road users. Capability depends on driver experience and training, hampered by fatigue, drugs, stress, distraction and effort. The combination of task demand and capability leads to either control over the vehicle, or loss of control, which may be compensated for by e.g. decrease of speed. |  |                         | 2 |   |   |   |   |   | road          |           |  |        | x      |        | <ul style="list-style-type: none"> <li>• [Fuller, 2000]</li> <li>• [Fuller &amp; Bonney, 2004]</li> </ul> |  |   |
| 811. | TDA (Task Demand Assessment)                | Step   | Mit     | 2010          | Aims to assess task difficulty and to propose better and efficient work practices. It assesses construction activities, based on characteristics of the activity and independent of the workers' capabilities, and analyzes how changes in operation parameters can affect potential of accidents.   |  |                         |   |   |   | 5 | 6 |   | manufacturing |           |  | x      |        |        | <ul style="list-style-type: none"> <li>• [Mitropoulos &amp; Nambodiri, 2011]</li> </ul>                   |  |   |

| 812. | TEACHER/<br>SIERRA<br>(Technique for<br>Evaluating and<br>Assessing the<br>Contribution of<br>Human Error to Risk<br>[which uses the]<br>Systems Induced<br>Error Approach) | Int    | HRA<br>,<br>Task | 1993                | Alternative HRA framework more aimed at lower consequence accidents than PSA traditionally aims at. It has a number of components. The first is SIERRA. This states that humans have basic error tendencies that are influenced by PIFs (Performance Influencing Factors). TEACHER focuses on defining a task inventory, then determining the prioritisation of critical tasks according to their risk potential, leading to a rating on a risk exposure index for each task. Following the screening analysis a HTA and PHEA analysis are carried out, following which, those errors with significant consequence potential are analysed with respect to a set of PIF audit questions, to develop remedies for the error. Each PIF audit question allows the analyst to rate the task according to, e.g., the extent to which procedures are defined and developed by using task analysis, on a seven-point semantic differential, anchored at each end-point. Risk reduction is then determined by the analyst. | Developed by D. Embrey.  |                         | 2 | 3 |   | 5 | 6 |   |   |               | (chemical)  |        |             | x      |        |            |   | • [Kirwan, Part 1, 1998] |
| 813. | Team CTA<br>(Team Cognitive<br>Task Analysis)   | Step   | Task             | 1982                | Team CTA considers the team as an intelligent entity that can be studied to aid team task design, team composition, team training. The model emphasizes the importance of communication, and shared situational awareness and focuses on "action teams". It can be used to diagnose and offer suggestions for treatment of existing problems in teamwork as well as to help design training materials for new team members by outlining the knowledge and skills required for team membership.  | Was developed on the notion that current methods of task analysis fail to capture team characteristics such as interdependence and co-operation. Applying a method of analysis designed for individuals to teams is not sufficient for true understanding of how a team works. |                         | 2 |   |   |   |   |   | 8 | nuclear, navy |             |        | x           |        | x      |            | • [Klein, 2000]<br>• [Klinger, 2003]<br>• [Salmon et al, 2004]<br>• [FAA HFW] |                          |
| 814. | Telelogic Tau   | Int    | Des              | 2001<br>or<br>older | Telelogic Tau provides specialised tool sets for every phase of a project: 1) Telelogic Tau UML Suite for requirement capture and analysis; 2) Telelogic Tau SDL Suite for design and implementation, and 3) Telelogic Tau TTCN Suite for comprehensive testing. In addition, a) SCADE Suite (sold to Esterel) facilitates the capture of unambiguous software specifications. It allows detecting corner bugs in the early stages of the development and reduces the coding and testing efforts. b) Telelogic Tau Logiscope Detects Coding Errors in C, C++, Ada and Java, Identifies and Locates Error-Prone Modules and Provides Code Coverage Analysis.   | Software tools that cover all phases of the development process: analysis, design, implementation and testing.   |                         |   | 3 |   | 6 |   |   |   | software      |             | x      |             |        |        |            | • [Telelogic Tau]   |                          |

| 815. | Temporal Logic  | Math   | Mod     | 1957          | Direct expression of safety and operational requirements and formal demonstration that these properties are preserved in the subsequent development steps. Formal Method. It extends First Order Logic (which contains no concept of time) by adding model operators. These operators can be used to qualify assertions about the system. Temporal formulas are interpreted on sequences of states (behaviours). Quantified time intervals and constraints are not handled explicitly in temporal logic. Absolute timing has to be handled by creating additional time states as part of the state definition.   | Useful as descriptive and demonstrative technique for small systems or small parts of large systems. Computer based tools are necessary for large systems. Related methods are Petri nets, finite state machines. Software requirements specification phase and design & development phase. |                         |   |   |   |   |   |   |   |         |             |        |        |        |        |            |  |  | <ul style="list-style-type: none"> <li>• [Bishop, 1990]</li> <li>• [EN 50128, 1996]</li> <li>• [Rakowsky]</li> </ul>   |
| 816. | TESEO (Tecnica Empirica Stima Errori Operatori (Empirical technique to estimate operator errors)) | Step   | Par     | 1980          | Assesses probability of operator failure. Used more as a tool of comparison between different designs of the man-machine system than for obtaining absolute probabilities. Human Error Probability (HEP) is the product of five values: (1) complexity of action, requiring close attention or not. (2) time available to carry out the activity. (3) experience and training of the operator. (4) operators emotional state, according to the gravity of the situation. (5) man-machine and environment interface.  | Developed in 1980 by G.C. Bello and C. Colombari (ENI Research Centre). Applicable to assessing operator failure in control rooms. Not considered very accurate.  |                         |   |   |   |   |   |   |   |         |             |        |        |        |        |            |  |  | <ul style="list-style-type: none"> <li>• [Humphreys, 1988]</li> <li>• [Bello &amp; Colombari, 1980]</li> <li>• [Mariani, 2012]</li> <li>• [MUFTIS3.2-I, 1996]</li> <li>• [GAIN ATM, 2003]</li> </ul> |
| 817. | Test Adequacy Measures  | Step   | Val     | 1972 or older | Aim is to determine the level of testing applied using quantifiable measures.  | See also Software Testing. See also Code Coverage.  |                         |   |   |   |   |   |   |   |         |             |        |        |        |        |            |  |  | <ul style="list-style-type: none"> <li>• [Bishop, 1990]</li> </ul>   |
| 818. | Test Coverage   | Gen    | SwD     | 1992 or older | For small pieces of code it is sometimes possible to achieve 100% test coverage. However due to the enormous number of permutations of states in a computer program execution, it is often not possible to achieve 100% test coverage, given the time it would take to exercise all possible states. Several techniques exist to reach optimum test coverage. There is a body of theory that attempts to calculate the probability that a system with a certain failure probability will pass a given number of tests. Monte Carlo simulation may also be useful. Test coverage should at least consider safety critical Must-Work-Functions and software safety requirements. | Some analysis is advisable to assess the optimum test coverage as part of the test planning process. See also Code Coverage.  |                         |   |   |   |   |   |   |   |         |             |        |        |        |        |            |  |  | <ul style="list-style-type: none"> <li>• [DO-178B, 1992]</li> <li>• [FAA00]</li> <li>• [Shahid et al., 2011]</li> <li>• [Shahid &amp; Ibrahim, 2011]</li> </ul>                                      |
| 819. | Test Results Analysis   | Step   | Val     | 2000 or older | Test Results Analysis aims to verify that all safety requirements have been satisfied. The analysis also aims to verify that all identified hazards have been eliminated or controlled to an acceptable level of risk. The results of the test safety analysis are provided to the ongoing system safety analysis activity. All test discrepancies of safety critical software should be evaluated and corrected in an appropriate manner.   |   |                         |   |   |   |   |   |   |   |         |             |        |        |        |        |            |  |  | <ul style="list-style-type: none"> <li>• [FAA00]</li> </ul>  |
| 820. | Tests based on Random Data  | Gen    | SwD     | 1984 or older | Software Testing technique. Aim is to cover test cases not covered by systematic methods. To minimise the effort of test data generation.  | Useful if there is some automated means of detecting anomalous or incorrect behaviour. See also Software Testing.   |                         |   |   |   |   |   |   |   |         |             |        |        |        |        |            |  |  | <ul style="list-style-type: none"> <li>• [Bishop, 1990]</li> </ul>   |

| 825. | THEA (Technique for Human Error Analysis) | Stat   | HRA     | 1997          | THEA is a technique designed for use by interactive system designers and engineers to help anticipate interaction failures. These may become problematic once designs become operational. The technique employs a cognitive error analysis based on an underlying model of human information processing. It is a highly structured approach, intended for use early in the development lifecycle as design concepts and requirements concerned with safety and usability – as well as functionality – are emerging. THEA employs a systematic method of asking questions and exploring interactive system designs based on how a device functions in a scenario. Steps are: 1. Detailed System Description; 2. Usage Scenarios; 3. Structure the scenarios (e.g. HTA); 4. Error Identification Error Consequence; 5. Underlying model of “human error”; 6. Suggestions for new requirements & Implications for design. | THEA aims to inform human-computer interface design at an early stage of development.   |                         | 2 | 3 | 4 | 5 | 6 |   |   |         | aviation, ATM |                                |        | x      |        |            |  |                                | • [Fields, 1997]<br>• [Pocock, 2001] |

| 826. | THERP<br>(Technique for Human Error Rate Prediction) | Tab, Stat | HRA     | 1981 | Aim is to predict human error probabilities and evaluate degradation of a man-machine system likely to be caused by human error, equipment functioning, operational procedures and practices, etc. Steps are: 1. Define the system failures of interest. 2. List and analyse the related human operations, and identify human errors that can occur, as well as relevant human error recovery modes. This stage of the process necessitates a comprehensive task and human error analysis. The tasks and associated outcomes are input to an HRAET (human reliability analysis event tree) in order to provide a graphical representation of a task's procedure. 3. Estimate the relevant human error probabilities (HEPs) for each sub-task, and enter these into the tree. 4. Estimate the effects of human error on the system failure events. 5. Recommend changes to the system and recalculate the system failure probabilities. | Developed by Swain & Guttman, Sandia Laboratories for the US Nuclear Regulatory Commission. Longest surviving HRA (Human Reliability Analysis) technique. Developed in 1960-1970; released in 1981. This technique is the standard method for the quantifying of human error in industry.   |                         |   |   |   |   | 5 |   |   |         |  | nuclear, defence, oil&gas, manufacturing, space |        |        | x      |            |   | <ul style="list-style-type: none"> <li>• [FAA00]</li> <li>• [Humphreys, 1988]</li> <li>• [Kirwan, 1994]</li> <li>• [Kirwan, Part 1, 1998]</li> <li>• [MUFTIS3.2-I, 1996]</li> <li>• [ΣΣ93, ΣΣ97]</li> <li>• [FAA HFW]</li> <li>• [Swain &amp; Guttman, 1983]</li> <li>• [GAIN ATM, 2003]</li> </ul> |
| 827. | Think-Aloud Protocol or Verbal Protocol              | Dat       | Task    | 1912 | Think aloud protocol, or Verbal protocol, is a technique applied in user testing where users are asked to vocalise their thoughts, feelings and opinions whilst interacting with a site as they perform a task. While the focus in user testing is primarily on how effectively a user performs the required tasks (and not on how users believe they are performing), verbalisations are useful in understanding situation awareness, mistakes that are made, getting ideas for what the causes might be and how the interface could be improved to avoid those problems.   | Method known already in the 1910s, but the theoretical framework for think-aloud protocol experiments is provided mainly by the work of Ericsson and Simon (1984, 1993). Two variations are Co-discovery, in which two participants jointly attempt to perform tasks together while being observed in a realistic work environment, and Cooperative Evaluation. |                         | 2 |   |   |   |   |   |   |         | social, healthcare, food, nuclear, chemical          |   |        |        | x      | x          | <ul style="list-style-type: none"> <li>• [FAA HFW]</li> <li>• [Nielsen, 1997]</li> <li>• [Thinkaloud]</li> <li>• [Bernardini, 1999]</li> <li>• [Kirwan &amp; Ainsworth, 1992]</li> <li>• More refs: see [Refs Think Aloud Protocol]</li> </ul>  |   |

| 832. | TOPAZ<br>(Traffic Organisation and Perturbation AnalyZer)       | Int    | OpR     | 1993 from | TOPAZ is a methodology aiming to systematically support all stages of the safety risk assessment of a novel operation in air traffic management, including the provision of effective safety feedback to operational concept design experts. The methodology integrates several individual safety techniques, such as Pure Hazard Brainstorming, TOPAZ hazard database, Hazard crystallization into safety relevant scenarios, Agent Based Modelling and Simulation (ABMS), formal modelling using the powerful Petri net formalism SDCPN, model Verification & Validation, Rare event Monte Carlo simulation, Bias and Uncertainty Assessment, and Risk mitigation brainstorming with operational experts. A complementary step is to use monitoring data to verify the assumptions adopted. The quantitative safety methods combined form the MA-DRM safety method in this list. Because Rare event MC simulation forms a key element within MA-DRM, for the particular application a choice can be made from various separately listed mathematical techniques such as: HSMP, Stochastic Differential Equations on Hybrid State Space, Generalised Reich Collision Risk Model, Risk decomposition and Interacting Particle System. | The TOPAZ methodology and several of its integrated safety assessment techniques have been developed by National Aerospace Laboratory NLR from 1993 onwards. Most individual safety techniques are separately described in this list. Supporting TOPAZ toolsets have been developed for many different conflict scenarios and operations. Applications include collision risk assessment between aircraft on parallel en route lanes, between aircraft in terminal manoeuvring area, between taxiing and landing aircraft at an airport, and between aircraft flying under airborne self-separation. | 1                       | 2 | 3 | 4 | 5 | 6 | 7 | 8         | ATM     | x           | x      | x      | x      | x      | <ul style="list-style-type: none"> <li>[Blom et al, 1998, 2001]</li> <li>[Blom &amp; Stroeve &amp; DeJong, 2006]</li> <li>[MUFTIS3.2-II, 1996]</li> <li>[GAIN ATM, 2003]</li> <li>[FAA HFW]</li> <li>[TOPAZ Applications]</li> </ul> |
| 833. | TOPAZ hazard database   | Dat    | Hzi     | 1999      | Database of hazards gathered using dedicated TOPAZ-based hazard brainstorming for various ATM operations.   | Technique used for TOPAZ-based hazard brainstorming is Pure hazard brainstorming, or Scenario-based hazard brainstorming.  |                         |   | 3 |   |   |   |   |           | ATM     | x           | x      | x      | x      | x      | <ul style="list-style-type: none"> <li>[TOPAZ hazard database]</li> </ul>  |

| 834. | TOPPE<br>(Team Operations Performance and Procedure Evaluation) | Step   | HRA     | 1991      | A procedure validation and team performance evaluation technique. It uses judges to evaluate team performance when carrying out emergency procedures. It is therefore not designed as a Human Error Identification tool. However, it can identify procedural errors (omissions, wrong procedural transitions etc.), and team leadership or co-ordination problems. As such, an approach could be developed to determine credible procedural and co-ordination errors of these types, based on observation of emergency exercises which all nuclear power plant utilities are required to carry out.   |  |                         | 3 |   |   |   | 7 |   | (nuclear) |         |             |        |        | x      |        | <ul style="list-style-type: none"> <li>[Kirwan, 1995]</li> <li>[Kirwan, Part 1, 1998]</li> </ul>   |

| 842. | TSA<br>(Test Safety Analysis)       | Step   | HzA     | 1979<br>or<br>older | Test Safety Analysis is used to ensure a safe environment during the conduct of systems and prototype testing. It also provides safety lessons to be incorporated into the design, as applicable. Each test is evaluated to identify hazardous materials or operations. Each proposed test needs to be analyzed by safety personnel to identify hazards inherent in the test and to ensure that hazard control measures are incorporated into test procedures. It is during the process of test safety analysis that safety personnel have an opportunity to identify other data that may be useful to safety and can be produced by the test with little or no additional cost or schedule impact. | A lessons learned approach of any new systems 'or potentially hazardous subsystems' is provided. This approach is especially applicable to the development of new systems, and particularly in the engineering/ development phase.  |                         |   |   |   |   |   |   | 6 |         |             | (space), (rail), (software) | x      |        |        |            |  |  | <ul style="list-style-type: none"> <li>• [FAA AC431]</li> <li>• [FAA00]</li> <li>• [ΣΣ93, ΣΣ97]</li> </ul>   |
| 843. | TTA<br>(Tabular Task Analysis)      | Tab    | Task    | 1989<br>or<br>older | Aim is to specify the context in which important task steps take place and to identify aspects that may be improved. The TTA usually follows on from a Hierarchical Task Analysis (HTA) and is columnar in format. It takes each particular task-step or operation and considers specific aspects, such as Who is doing the operation, What displays are being used.  | Is useful for dynamic situations which involve a considerable amount of decision-making.  |                         |   | 2 |   |   |   |   |   |         |             | ATM, nuclear                |        |        | x      |            |  | <ul style="list-style-type: none"> <li>• [Kirwan, 1994]</li> <li>• [Vinnem, 2000]</li> </ul> |  |

| 844. | UML<br>(Unified Modelling Language) | Int    | Des     | 1997                | UML is the industry-standard language for specifying, visualising, constructing, and documenting the artefacts of software systems. It simplifies the complex process of software design, making a "blueprint" for construction.  |   |                         | 2 |   |   |   |   |   |   |         |             | software                    |        | x      |        |            |  |  | <ul style="list-style-type: none"> <li>• [UML]</li> </ul>  |
| 845. | Uncertainty Analysis                | Gen    | Val     |                     | Uncertainty Analysis addresses, quantitatively and qualitatively, those factors that cause the results of an assessment to be uncertain. Uncertainty generally has two types of impact on the assessed risk level: Bias and Variation. Important components of uncertainty analysis include qualitative analysis that identifies the uncertainties, quantitative analysis of the effects of the uncertainties on the decision process, and communication of the uncertainty. The analysis of the uncertainty depends on the problem. Differences result from differences in spatial and temporal scale, available data and information, models and objectives.                                      | Uncertainty analysis covers a wide range of techniques, from simple descriptive procedures to quantitative estimation of uncertainty, to more formal decision-based procedures. The analysis may be qualitative or quantitative, depending on the level of resolution required and the amount of information available. The assessment of uncertainty is also tied to the view of uncertainty from the scientist and risk manager. Sometimes known as Error Propagation. See also Bias and Uncertainty Assessment. See also Sensitivity Analysis. |                         |   |   |   |   |   | 5 |   |         |             | all                         | x      | x      | x      | x          |  |  | <ul style="list-style-type: none"> <li>• [FAA00]</li> <li>• [ΣΣ93, ΣΣ97]</li> <li>• [Smith, 2002]</li> <li>• [Morgan &amp; Henrion, 1990]</li> </ul> |

| 846. | Unused Code Analysis   | Gen    | SwD       | 1996 or older | A common coding error is to generate code that is logically excluded from execution; i.e., preconditions for the execution of this code will never be satisfied. There is no specific technique for identifying unused code; however, unused code is often identified during the course of performing other types of code analysis. It can be found during unit testing with COTS coverage analyser tools.  | Unused code is undesirable for three reasons; a) it is potentially symptomatic of a major error in implementing the software design; b) it introduces unnecessary complexity and occupies memory or mass storage which is often a limited resource; and c) the unused code might contain routines which would be hazardous if they were inadvertently executed (e.g., by a hardware failure or by a Single Event Upset). See also Code Coverage. |                         |   |   | 3 |   |   |   |   |         |                                |        |        |        |        |            |  |  | <ul style="list-style-type: none"> <li>• [FAA00]</li> <li>• [NASA-GB-1740.13-96]</li> <li>• [Rakowsky]</li> </ul>               |

| 847. | User Analysis  | Gen    | Dat, Task |               | Aims to describe the user population in order to identify user specific factors impacting the task(s). Components to be considered include: Usage Objectives, User Roles, User Characteristics, Usage Environment, User Interface Guidelines.   | Some user factors to consider include knowledge, skills, limitations, experience, age, height, size, weight, strength, maturity, and many other considerations.  |                         |   | 2 |   |   |   |   |   |         |                                |        |        |        |        |            |  |  | <ul style="list-style-type: none"> <li>• [FAA HFW]</li> <li>• [Do &amp; Gatica, 2010]</li> </ul>                                |
| 848. | V&V (Verification and Validation)  | Gen    | Val       | 1982 or older | Verification: to build the product right (which refers to product specifications); Validation: to build the right product (which refers to user's needs).   | Essential for safety-related systems. Tools available. Several frameworks for validation and/or verification exist, e.g. E-OCVM or SAFMAC, but numerous safety methods in this database are applicable to V&V activities.  |                         |   |   |   |   |   |   | 7 | 8       | all                            | x      | x      |        |        |            |  |  | <ul style="list-style-type: none"> <li>• [Bishop, 1990]</li> </ul>  |
| 849. | VDM (Vienna Development Method)  | Math   | Des       | 1972          | Systematic specification and implementation of sequential programs. Formal Method. Mathematically based specification technique and a technique for refining implementations in a way that allows proof of their correctness with respect to the specification. The specification language is model-based in that the system state is modelled in terms of set-theoretic structures, on which defined invariants (predicates) and operations on that state are modelled by specifying their pre-and post conditions in terms of the system state. Operations can be proved to preserve the system invariants. | The origins of VDM specification language lie in the IBM Laboratory in Vienna where the first version of the language was called the Vienna Definition Language (VDL). Recommended especially for the specification of sequential programs. Established technique, training courses available. Closely related to Z. Tools available. Software requirements specification phase and design & development phase.                                  |                         |   | 2 |   |   |   |   | 6 |         | electronics, finance, avionics |        | x      |        |        |            |  |  | <ul style="list-style-type: none"> <li>• [Bishop, 1990]</li> <li>• [EN 50128, 1996]</li> </ul>                                  |
| 850. | VEMER (Veiligheid, Efficiency en Milieu Effect Rapportage, i.e. Safety Efficiency and Environment (SEE) Framework) | Int    | OpR       | 2004          | VEMER is a frame of reference for the definition of the quality of LVNL's Air Traffic Management (ATM) Service Provision. The Safety Assessment takes place within the broader context of a trade-off between safety, efficiency and environment. The framework uses two iterative Mechanisms: I. Formulation of SEE targets, Generation of scenarios, Definition of question, scope & level of detail, and Selection of SEE Model. II. SEE evaluation for the generated scenarios using the selected SEE Model, using the ATM system description or a concept of operation as input.                         | LVNL is the main air navigation service provider in the Netherlands.   | 1                       | 2 | 3 | 4 | 5 | 6 | 7 | 8 |         | ATM                            | x      | x      | x      | x      | x          |  |  | <ul style="list-style-type: none"> <li>• [VEM, 2004]</li> <li>• [LVNL Safety Criteria]</li> <li>• [Bos et al., 2007]</li> </ul> |

| 851. | Vital Coded Processor                  | Step   | Mit       | 1989          | Aim is to be fail-safe against computer processing faults in the software development environment and the computer hardware. In this technique, three types of errors – operation, operator and operand errors – can be detected by redundant code with static signatures.  | Overcomes most of the insecurities associated with microprocessor-based technology. Useful on relatively simple applications that have a safe state. See also Fail Safety. See also Memorizing Executed Cases.   |                         |   |   |   |   |   |   |   | 6       |             |                      | rail   | x      | x      |            |   |  |   | • [Bishop, 1990]  |
| 852. | VTLA (Vertical Timeline Analysis)      | Tab    | Task, HFA | 1987 or older | Investigates workload and crew co-ordination, focuses on crew activities and personnel. A series of columns are used: task; sub-task (action) description; time the sub-task begins; time the sub-task ends; and a column each for the operators involved in the whole task/scenario, indicating in each row which operators are involved in the sub-task. If an operator moves from their usual location this is noted under the column for that operator at the time it happens. The VTLA helps to identify where team co-ordination will be particularly required, and also where workload may be unevenly spread, and where human resources may be insufficient. The VTLA can also discriminate between actions and monitoring, and can show potential actions given other plant failures or system recoveries. Lastly, key system/transient events can be indicated on the x-axis. | See also HTLA. See also Timeline Analysis. VTLA focuses on crew activities and personnel whereas HTLA focuses on task sequencing and overall timing.   |                         |   | 2 |   |   | 4 | 5 |   |         |             | (nuclear), (oil&gas) |        |        |        | x          | x |  |   | • [Kirwan & Kennedy & Hamblen]<br>• [Kirwan, 1994]<br>• [Task Time] |
| 853. | WAAS (World Aircraft Accident Summary) | Dat    | Dat       | 1990          | Provides brief details of all known major operational accidents involving air carriers operating jet and turboprop aircraft and helicopters and the larger piston-engined types worldwide.  | WAAS was produced on behalf of the British Civil Aviation Authority, by Airclaims Limited. A subset, containing data and descriptive information about all known fatal airline accidents with passenger fatalities for the last ten years, was purchased by FAA. |                         |   |   |   |   |   |   |   |         | 8           | aviation, aircraft   | x      |        |        |            | x |  | • [WAAS Database]<br>• [ER Library - Aviation Safety]   |   |
| 854. | Walk-Through Task Analysis             | Step   | Task      | 1986          | This technique is a systematic analysis that can be used to determine and correct root causes of unplanned occurrences related to maintenance.  | This technique is applicable to maintenance. See also Inspections and Walkthroughs.  |                         |   |   | 3 |   |   |   |   |         | 7           | (energy), (nuclear)  |        |        |        | x          | x |  | • [FAA00]<br>• [EN 50128, 1996]<br>• [Kirwan & Ainsworth, 1992]<br>• [Kirwan, 1994]<br>• [ΣΣ93, ΣΣ97] |   |
|      | Walkthroughs                           |        |           |               |   | See Inspections and Walkthroughs   |                         |   |   |   |   |   |   |   |         |             |                      |        |        |        |            |   |  |   |   |
| 855. | Watchdog timers                        | Gen    | Des       | 1977 or older | Watchdog timers are hardware devices with the capability to reset (reboot) the system should the watchdog not be periodically reset by software. The computer has to “say hello” from time to time to the watchdog hardware to let it know that it is still alive. If it fails to do that then it will get a hardware reset. Aim is to provide a non-software related reliable hardware checking method of the software operation.  | Useful on all safety critical and real-time control systems. Related to software time-out checks. Sometimes referred to as Computer Operating Properly timer.  |                         |   |   |   |   |   |   | 6 |         |             | electronics, space   | x      | x      |        |            |   |  | • [Bishop, 1990]<br>• Internet  |   |

| 856. | WBA<br>(Why-Because<br>Analysis) | Stat   | HZA,<br>Ret | 1998                | Why-Because Analysis (WBA) is a rigorous technique for causally analysing the behaviour of complex technical and socio-technical systems. WBA is based on a rigorous notion of causal factor. Whether one event or state is a necessary causal factor in the occurrence of another is determined by applying the Counterfactual Test. During analysis, a Why-Because Graph (WB-Graph or WBG) is built showing the (necessary) causal connections between all events and states of the behaviour being analysed. The completed WBG is the main output of WBA. It is a directed acyclic graph where the nodes of the graph are factors. Directed edges denote cause-effect relations between the factors.   | WBA primary application is in the analysis of accidents, mainly to transportation systems (air, rail and sea). It is also used in the Ontological Analysis method for safety requirements analysis during system development. |                         |   |   |   | 4 |   |   |   |         |             |        |        |        |        |            |  |  | <ul style="list-style-type: none"> <li>• [WBA Homepage]</li> <li>• [Ladkin &amp; Loer, 1998]</li> </ul>                   |

| 857. | What-If Analysis                 | Step   | Hzi         | 1992<br>or<br>older | What-If Analysis methodology identifies hazards, hazardous situations, or specific accident events that could produce an undesirable consequence. The procedure is: 1. Define the activity or system of interest. 2. Define the problems of interest for the analysis. 3. Subdivide the activity or system for analysis. 4. Generate what-if questions for each element of the activity or system. 5. Use a team of subject matter experts to respond to each of the what-if questions, and develop recommendations for improvements wherever the risk of potential problems seems uncomfortable or unnecessary. 6. Further subdivide the elements of the activity or system (if necessary or otherwise useful); generally, the goal is to minimize the level of resolution necessary for a risk assessment. 7. Evaluate recommendations from the analysis and implement those that will bring more benefits than they will cost in the life cycle of the activity or system. | An example of a What-If analysis is Scenario Process Tool. Another variation of What-if analysis is Sensitivity Analysis. | 861. | Workload Analysis                  | Gen    | Task      | 1986 or older | Provides an appraisal of the extent of operator or crew task loading, based on the sequential accumulation of task times. Method permits an evaluation of the capability of the operator or crew to perform all assigned tasks in the time allotted by mission constraints. As capability is confirmed, hardware design requirements can be more precisely designated. If limitations are exposed, alternate function allocations and operator or crew task assignments are considered and implemented.   | See also CWA (Cognitive Workload Analysis).  |                         | 2 |   |   |   |   |   | 6 |         |             |        | defence, electronics                | x      |        | x          |  |   |   | <ul style="list-style-type: none"> <li>• [MIL-HDBK, 1999]</li> </ul>  |
| 862. | WPAM (Work Process Analysis Model) | Int    | Org, Task | 1994          | Safety management assessment linked to PSA-type of approach. The first part (WPAM-I) is qualitative; basically a task analysis is performed on the work process to which the tasks involved, actions and the defences in the task, and their failure modes are investigated. Next, the organisational factors matrix is defined for each key work process. The organisational factors influencing each task in the given work process are then ranked according to their importance. WPAM-II is next used to modify minimal cut set frequencies to include organisational dependencies among the PSA parameters, i.e. candidate parameter group. The next step in the WPAM-II is quantification. SLIM is used to find new frequencies for each minimal cut set. | WPAM may double-count the dependence of the organisational factors, if the HEPs used have already taken into the account the underlying factors, which may at times be implicitly modelled.  |                         | 2 | 3 | 4 | 5 |   |   |   |         |             |        | nuclear                             |        |        |            |  | x | x | <ul style="list-style-type: none"> <li>• [Kennedy &amp; Kirwan, 1998]</li> </ul>  |

| 866. | ZHA<br>(Zurich Hazard Analysis)             | Step   | HZA              | 1981 | Aims to identify and manage various types of hazards from a risk perspective. Steps are: 1) Define the scope; 2) Choose the team and team leader; 3) Identify hazards, define and assess hazard scenarios; 4) Build the risk profile, set the risk tolerance boundary and plot the risks; 5) Develop risk improvement actions; 6) Implement the risk improvements; 7) Review the analysis. Step 3 uses team brainstorming following a defined route (pathway) through the scope of the analysis, encouraged by a set of thought-provoking words (tickler list). In step 4, the risk profile is a matrix divided into four severity categories and six probability levels; the risk tolerance boundary is a line drawn across the risk profile. | Developed by Zurich Insurance Company, Switzerland.  | 1                       | 2 | 3 | 4 | 5 | 6 | 7 |   |         | manufacturing,<br>electronics,<br>chemical, food,<br>finance | x      |        |        | x      |            |  | <ul style="list-style-type: none"> <li>• [ZIC, 1998]</li> </ul>   |

## Part 2: Statistics

This Part provides statistics on the following details for each of the 866 methods as collected in Part 1:

- **A. Format**, specifies the general format of the method, e.g. whether it is a stepped approach, or a mathematical model, or a combination of various techniques, etc.
- **B. Purpose**, specifies the primary purpose of the method, e.g. whether it is for data gathering, for hardware dependability analysis, for human reliability analysis, etc.
- **C. Year**, i.e. year of development of the method. If uncertain, then words like ‘about’ or ‘or older’ are added.
- **D. Safety assessment stage**, which lists the stages of a generic safety assessment process, proposed in [SAP 15], during which the method can be of use. These stages are: **1)** Scope the assessment; **2)** Learning the nominal operation; **3)** Identify hazards; **4)** Combine hazards into risk framework; **5)** Evaluate risk; **6)** Identify potential mitigating measure to reduce risk; **7)** Safety monitoring and verification; **8)** Learning from safety feedback.
- **E. Domains**, i.e. the domains of application the method has been used in, such as nuclear, chemical, ATM (air traffic management), rail, healthcare.
- **F. Application**, i.e. is the method applicable to hardware, software, human, procedures, or to organisation.

### A. Statistics on classes defined for Format column:

The Safety Methods Database provides information on the format of each method, defined by the classes in the table below. The last column and the graph provide statistics on the number of methods collected for each class.

| Classes in Format column |   | Nr of methods |
|--------------------------|---|---------------|
| Gen                      | Generic term or principle or theory, rather than a specific technique             | 117           |
| Step                     | Stepped approach or technique or specific way of working                          | 175           |
| Tab                      | Static approach with tabular, checklist or questionnaire support                  | 139           |
| Stat                     | Static model or approach with graphical support (e.g. flow charts, trees, graphs) | 144           |
| Dyn                      | Dynamic model with graphical support, often with mathematical base                | 23            |
| Math                     | Mathematical formalism or expression, with no or limited graphical support        | 57            |
| Int                      | Framework or Integrated method of more than one technique                         | 99            |
| Dat                      | Database or data collection tool  | 73            |
| Min                      | Data analysis tool or data mining tool  | 14            |
| RTS                      | Real-time simulation  | 23            |
| FTS                      | Fast-time simulation  | 24            |

## B. Statistics for classes defined for Purpose column:

The Safety Methods Database provides information on the purpose of each method, defined by the classes in the table below. The last column and the graph provide statistics on the number of methods collected for each class. In some cases one method may have multiple purposes, which is why the total may add up to be larger than the number of methods collected.

| Classes in Purpose column |  | Nr of methods |
|---------------------------|--|---------------|
| Mod                       | Developing a model (e.g. as input to or as part of analysis)   | 97            |
| Par                       | Parameter value assessment (e.g. human error probabilities, failure frequencies)                               | 22            |
| HRA                       | Human Reliability Analysis or Human Error analysis method  | 88            |
| HFA                       | Human Factors Analysis (beyond reliability; e.g. behaviour, situation awareness)                               | 46            |
| Task                      | Human Task analysis  | 79            |
| Trai                      | Training technique or method to analyse training   | 13            |
| Des                       | Design technique (about making/ensuring a safe design, rather than about analyzing whether the design is safe) | 72            |
| Dec                       | Decision-making  | 27            |
| SwD                       | Software dependability analysis or Software testing technique  | 68            |
| HwD                       | Hardware dependability analysis (reliability, maintainability, availability, etc)                              | 24            |
| OpR                       | Risk analysis of an operation or of a safety-critical scenario   | 58            |
| Org                       | Organisation, Safety management, or Safety culture assessment  | 36            |
| Dat                       | Data collection and information sharing  | 78            |
| Mit                       | Mitigation of risk   | 56            |
| HZI                       | Identification of hazards /safety concerns /causes /issues   | 42            |
| HZA                       | Identification and analysis of frequency and/or severity of hazards / safety concerns / causes / issues        | 88            |
| Col                       | Collision risk analysis or Conflict risk analysis, typically between aircraft                                  | 16            |
| Val                       | Validation, Verification, Bias and uncertainty analysis, Documentation/Tracking, and Oversight/Monitoring      | 36            |
| Ret                       | Retrospective accident or event analysis   | 56            |

### C. Statistics for classes defined for Year:

The Safety Methods Database also indicates the method's year of development. For 17 of the 866 methods collected, this information was not available. For some other methods, only an estimated year could be identified, and for others only a 'latest' year is available, i.e. the method existed in that year, but it is possible that it was developed earlier than that. Statistics on the number of methods developed in each period of time are provided in the table and the figure below. The oldest methods are Quality Assurance (2500 BC), Error Detection and Correction (150 AD), Logic Diagrams (300 AD for 'Porphyrian trees'; the modern Logic Diagram Dates from 1761), Data Mining (1750), Monte Carlo simulation (1777), Wind/Tornado Analysis (1888), Neural networks (1890), Factor analysis (1900), Markov chains (1906) and Pareto charts (1906).

| Years         | Number     | Percentage   |
|---------------|------------|--------------|
| 2010-2020     | 27         | 3 %          |
| 2000-2009     | 148        | 17 %         |
| 1990-1999     | 289        | 33 %         |
| 1980-1989     | 177        | 20 %         |
| 1970-1979     | 106        | 12 %         |
| 1960-1969     | 44         | 5 %          |
| 1950-1959     | 25         | 3 %          |
| 1940-1949     | 11         | 1 %          |
| 1930-1939     | 4          | 0 %          |
| 1920-1929     | 5          | 1 %          |
| 1910-1919     | 3          | 0 %          |
| 1900-1909     | 3          | 0 %          |
| 1800-1899     | 2          | 0 %          |
| Before 1799   | 5          | 1 %          |
| Not specified | 17         | 2 %          |
| <b>Total</b>  | <b>866</b> | <b>100 %</b> |

#### D. Statistics on coverage of eight stages of generic safety assessment process

The Safety Methods Database also indicates in which stages of the generic safety assessment process the method can be of use; these stages are explained in [SAP 15]. A summary distribution of methods among the eight stages is given below.

| Stages of generic safety assessment process                     | Number | Percentage |
|---|--------|------------|
| Stage 1 (Scope the assessment)                                  | 32     | 4 %        |
| Stage 2 (Learning the nominal operation)                        | 170    | 20 %       |
| Stage 3 (Identify hazards)                                      | 259    | 30 %       |
| Stage 4 (Combine hazards into risk framework)                   | 216    | 25 %       |
| Stage 5 (Evaluate risk)   | 285    | 33 %       |
| Stage 6 (Identify potential mitigating measures to reduce risk) | 220    | 25 %       |
| Stage 7 (Safety monitoring and verification)                    | 119    | 14 %       |
| Stage 8 (Learning from safety feedback)                         | 150    | 17 %       |

The following chart shows how many methods address multiple stages.

The following table shows how many methods address which combinations of stages.

| # stages | Stages of Generic Safety Assessment process |   |   |   |   |   |   |   | Number of methods in this class |    |
|----------|---|---|---|---|---|---|---|---|---------------------------------|----|
|          | 1   | 2 | 3 | 4 | 5 | 6 | 7 | 8 |                                 |    |
| 8        | x   | x | x | x | x | x | x | x | 6                               | 6  |
|          | x   | x | x | x | x | x | x |   | 5                               | 7  |
| 7        | x   | x | x | x | x | x |   | x | 2                               |    |
|          | 6   | x | x | x | x | x | x |   |                                 | 2  |
|          |   | x | x | x | x | x | x |   | 5                               |    |
| 5        | x   | x | x | x | x |   |   |   | 1                               | 5  |
|          |   | x | x | x | x | x |   |   | 2                               |    |
|          | x   |   | x | x | x | x |   |   | 1                               |    |
|          |   | x | x | x | x |   |   | x | 1                               |    |
| 4        | x   | x | x | x |   |   |   |   | 1                               | 22 |
|          | x   | x |   | x | x |   |   |   | 1                               |    |
|          | x   |   |   | x | x | x |   |   | 1                               |    |
|          |   | x | x | x | x |   |   |   | 3                               |    |

### E. Statistics for classes defined for Domain column:

The Safety Methods Database covers many domains of application, such as aviation, nuclear industry, chemical industry, manufacturing industry, etc. For each method the Database indicates the domains of application to date. Note that for some methods we found proof or a strong indication that method has in fact been applied in this domain; statistics on this are provided in column 'Applied' below. For some methods we found indication that the method is (apparently) intended for application in this domain, but found no strong indication (yet) that the method has in fact been applied; statistics on this are provided in column '(Applicable)' below. For some methods, no applications were found (yet), not even in an example illustration, so that the domain is currently unclear. Finally, there are a few approaches that are very generic and that have been used in virtually all domains.

| Classes in Domain column |   | Applied | (Applicable) | Total |
|--------------------------|---|---------|--------------|-------|
| Aviation                 | Operation of individual aircraft or aircraft fleets, including pilot and crew factors and airline operations  | 145     | 26           | 171   |
| Airport                  | Airport operations and airport design   | 23      | 6            | 29    |
| ATM                      | Air traffic management and air traffic control  | 152     | 32           | 184   |
| Aircraft                 | Aircraft technical systems and airworthiness issues. Also including rotorcraft such as helicopters.   | 81      | 16           | 97    |
| Avionics                 | Electronic systems used on aircraft, satellites, and spacecraft, including communication, navigation, cockpit display.  | 31      | 20           | 51    |
| Defence                  | Military, on land or in the air, including military aviation, weapon systems and nuclear weapon systems. Excluding military at sea.   | 104     | 13           | 117   |
| Navy                     | Navy, military at sea, including sub-marines  | 38      | 5            | 43    |
| Space                    | Space safety, including spacecraft, satellites, space missions. Excluding aircraft, excluding avionics.   | 59      | 23           | 82    |
| Rail                     | Rail transport and operation of trains, including railway design. Excluding manufacturing of trains.  | 60      | 8            | 68    |
| Road                     | Road transport and operation of cars, including road design, tunnels. Excluding manufacturing of cars.  | 49      | 1            | 50    |
| Maritime                 | Marine, maritime or inland water transport, e.g. ships, vessels, ferry's, and coast guard search and rescue. Excluding navy, sea pollution, oil spills.   | 26      | 2            | 28    |
| Nuclear                  | Nuclear power industry. Excluding nuclear weapon systems.   | 198     | 32           | 210   |
| Energy                   | Energy or electricity-generating plants, solar energy, windturbines, thermal power plants. Excluding nuclear power.   | 25      | 3            | 28    |
| Chemical                 | Chemical industry and processes, including production of medicine, biochemical industry. Excluding oil&gas, petrochemical, food and beverages.  | 98      | 6            | 104   |
| Oil&gas                  | Oil and/or gas industry, including offshore oil&gas industry, petrochemical industry  | 86      | 7            | 93    |
| Manufacturing            | Manufacturing plants, including automotive or automobile manufacturing, construction of buildings, ship building, and process industry (i.e. processing of bulk resources into other products). Excluding food, chemical or petrochemical industry. | 85      | 8            | 93    |
| Healthcare               | Health care, hospitals, nursing, medical operations, biomedical issues. Excluding production of medicine and other chemicals, and excluding ergonomics.   | 116     | 6            | 122   |
| Environment              | Environment safety, e.g. air pollution, sea pollution, fuel and oil spills, wastewater treatment plants, fish and wildlife reserves, biology, earthquakes, water management   | 47      | 1            | 48    |
| Food                     | Food and beverages, including public water supply systems, agriculture  | 28      | 1            | 29    |
| Mining                   | Mining industry   | 12      | 1            | 13    |
| Social                   | Psychology, psychometrics, behavioural sciences, social sciences, education, safety culture studies.  | 45      | 2            | 47    |
| Ergonomics               | Ergonomics, i.e. workplace equipment design, intending to reduce operator fatigue and discomfort. Also including household safety   | 15      | 2            | 17    |
| Finance                  | Finance, banking, insurance, economics  | 44      | 1            | 45    |
| Management               | Management and organisation, including project management, information management, product management, marketing,   | 55      | 0            | 55    |

|                 |  |    |   |    |
|-----------------|--|----|---|----|
|                 | operations research, logistics.  |    |   |    |
| Security        | Security, i.e. dealing with protection from harm due to intentional criminal acts such as assault, burglary or vandalism. Excluding police and fire fighting | 22 | 1 | 23 |
| Leisure         | Leisure and amusement industry, amusement parks, games, video games, media (e.g. tv advertisements), leisure-related search and rescue                       | 16 | 0 | 16 |
| Police          | Police and Fire fighting, including forensics and law.   | 23 | 1 | 24 |
| Electronics     | Electronics, electronic equipment, telecommunications, digital forensics   | 69 | 3 | 72 |
| Software        | Method has been applied to software design or analysis, but the industry sector in which the software is actually used is unclear or unspecified.            | 87 | 5 | 92 |
| No-domain-found | No applications were found (yet) for this method, not even in an example illustration, so that the domain is currently unclear.                              | 11 | 0 | 11 |
| All             | There are a few approaches that are very generic and that have been used in virtually all domains.   | 14 | 0 | 14 |

## F. Statistics on coverage of concept aspects (columns ‘Hw’, ‘Sw’, ‘Hu’, ‘Pr’, ‘Or’)

Finally, another detail provided for each method listed in the Safety Methods Database is whether it is aimed at assessing Hardware aspects, Software aspects, Human aspects, Procedures, or Organisation. Some Statistics on these results are given below.

| Concept aspects | Number | Percentage |
|-----------------|--------|------------|
| Hardware        | 441    | 51 %       |
| Software        | 278    | 32 %       |
| Human           | 416    | 48 %       |
| Procedures      | 267    | 31 %       |
| Organisation    | 161    | 19 %       |

Note that one method may cover several of these concept aspects, so some methods are counted more than once. The following table shows how many methods cover which of these aspects.

|           | Hardware   | Software   | Human      | Procedures | Organisation | Number of methods in this class |            |
|-----------|------------|------------|------------|------------|--------------|---------------------------------|------------|
| 5 aspects | x          | x          | x          | x          | x            | 52                              | 52         |
| 4 aspects | x          | x          | x          | x          |              | 14                              | 33         |
|           | x          | x          | x          |            | x            | 0                               |            |
|           | x          | x          |            | x          | x            | 0                               |            |
|           | x          |            | x          | x          | x            | 19                              |            |
|           |            | x          | x          | x          | x            | 0                               |            |
| 3 aspects | x          | x          | x          |            |              | 11                              | 89         |

|           |            |            |            | x          | 32           |                                 |            |
|           | <b>441</b> | <b>278</b> | <b>416</b> | <b>267</b> | <b>161</b>   | <b>866</b>                      | <b>866</b> |

One may see that there are a lot of methods (i.e. 480 methods, or 55%) that cover one concept aspect only.
